Preface

Reader information

The SINUMERIK documentation is divided into 4 different levels:

- General Documentation
- User Documentation
- Manufacturer/Service Documentation
- OEM Documentation

This documentation is intended for the manufacturers of machine tools. It provides a detailed description of the functionality of the SINUMERIK 840D and SINUMERIK FM-NC control systems.

The Descriptions of Functions only apply to the software versions specified. When a new software version is published, the Description of Functions for that software should be ordered. Old Descriptions of Functions are not necessarily applicable to new software versions.

Please consult your local Siemens office for more detailed information about other SINUMERIK 840D and SINUMERIK FM-NC publications as well as the publications that apply to all SINUMERIK controls (e. g. Universal Interface, Measuring Cycles, ...).

Note

Other functions not described in this documentation might be executable in the control. This does not, however, represent an obligation to supply such functions with a new control or when servicing.

Aim

The Description of Functions provides the information required for configuration and installation/start-up.

Target groups

The Description of Functions therefore contains information for:

- The configuring engineer
- The PLC programmer who writes the PLC user program by providing signal lists
- The system start-up engineer after configuration and installation of the machinery and equipment
- The service technician for checking and interpreting the status displays and alarms

Note on using the manual

This manual is structured as follows:

- General list of contents of the manual
- Functional descriptions in alphanumeric order according to the codes used for the Description of Functions
- Appendix with general index
Note
The Description of Functions Basic Machine (Part 1) contains both a general index as well as a reference list, a lexicon and an index of abbreviations.

Pages indicated provide the following information:
Part of the Description of Functions / Book / Chapter / Section - Page

If you require information on a certain function, you will find the function as well as the code under which the function is organized on the inside title page of the manual.

If you only require information on a certain term please refer to the index in the Appendix. There you will find the code of the Description of Functions, the Chapter/Section number as well as the page number on which the information about this term is to be found.

Within each of the Description of Functions in Chapters 4 and 5 you will find definitions on effect, data format, input limits etc. for the various signals and data definitions. These definitions are explained in the Technical Comments section below.

Important
This documentation applies to:
- SINUMERIK 840D or SINUMERIK FM-NC control,
  software version 4
- SINUMERIK 810D control,
  software version 2

Specification of the software version
The software versions specified in this documentation refer to the SINUMERIK 840D control; the parallel software version for the SINUMERIK 810D control (if the function is released, see /BU/, Catalog NC 60.1) is not specified explicitly. The following applies:

Table 1-1 Equivalent software versions

Technical Comments

Notation

The following notation and abbreviations are used in this documentation:

- PLC interface signals \( \rightarrow \) IS “Signal name” (signal data)
  
  E.g.:
  
  - IS “MMC-CPU1 ready” (DB10, DBX108.2), i.e. the signal is stored in data block 10, data byte 108, bit 2.
  - IS “Feed/spindle speed override” (DB31-48, DBB0), i.e. the signals are stored for specific axes/spindles in data blocks 31 to 48, data block byte 0.

- Machine data \( \rightarrow \) MD: MD_NAME

- Setting data \( \rightarrow \) SD: SD_NAME

- The character “\( \div \)” means “corresponds to”

Explanation of the abbreviations used in Chapt. 4 and 5

In Chapters 4 and 5 of the Description of Functions you will find a description of the data and signals that bear relevance to the function concerned. Terms and abbreviations used in these tabular descriptions are explained here.

Values in the table

The machine data indicated in the Descriptions of Functions are always values for an NCU572.

For the values of the other NCUs (e.g. NCU570, NCU571, NCU573), please refer to the “Lists” documentation.

References: /LIS/ “Lists”

Default value

The machine/setting data is preset with this value during installation. If these default values are different for each channel, this is marked by an “/”.

Value range (minimum and maximum value)

States the input limits. If no value range is specified, the input limits are dependent on the data type and “\( \div \div \div \) is displayed next to the field.

Activation

When machine data, setting data etc. are altered they are not immediately active. Information about activation of alterations is therefore always stated. The following is a list of the possible activation conditions in order of priority:

- POWER ON (po) “RESET” key on the front panel of the NC module or by switching the power off/on
- NEW_CONF (cf) “Re-configuring” of PLC interface function
- RESET (re) “RESET” key on operator panel, or
- Immediately (im) After input of value
Protection levels

Protection levels 0–7 are available, the protection of levels 0 to 3 (4 to 7) can be removed by setting a password (keyswitch setting). The user only has access to information for a certain protection level or for the lower protection levels. The machine data are assigned different protection levels as standard.

The table lists write protection levels only because read protection levels are derived from the write protection levels:

<table>
<thead>
<tr>
<th>Write protection level</th>
<th>Read protection level</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
</tr>
</tbody>
</table>

References:  
/BA/, "Operator’s Guide"  
/FB/, A2, "Various Interface Signals"

Unit

The unit refers to the machine data default setting  
SCALING_FACTOR_USER_DEF_MASK and  
SCALING_FACTOR_USER_DEF.

If the MD is not based on a physical unit a "-" is entered.

Data type

The following data types are used in the control:

- **DOUBLE**  
  Real or integer values (values with decimal point or integers)  
  Inputs limits from +/-4.19*10^-307 to +/-1.67*10^308

- **DWORD**  
  Integer values  
  Input limits from -2.147*10^9 to +2.147*10^9

- **BOOLEAN**  
  Possible input values: true or false or 0 or 1

- **BYTE**  
  Integer values from -128 to +127

- **STRING**  
  Consisting of max. 16 ASCII characters (capital letters, digits and underscore)

Data management

The PLC interface descriptions in the individual Descriptions of Functions assume a theoretical maximum number of components:

- 4 mode groups (associated signals stored in DB11)
- 8 channels (associated signals stored in DB21-30)
- 31 axes (associated signals stored in DB31 to 61)

For the number of components actually implemented for each of the software versions, please consult

Brief Description

General remarks

Signals can be read and output in the interpolation cycle via the “digital and analog NCK I/Os”. The following functions can be executed with these signals, for example:

- Several feed values in one block
- Several auxiliary functions in a block
- Rapid retraction on finished contour
- Axis-specific delete distance-to-go
- Program branching
- Rapid NC start
- Analog calipers
- Position switching signals
- Punching/nibbling functions
- Analog value control
- etc.

Contents

The specific features and operating characteristics of the digital and analog I/Os are described in this document. A reference to further relevant documentation (“References”) is given with respect to every function that uses the I/Os.
1 Brief Description

Notes
Detailed Description

2.1 General functionality

General
The ability to control or influence time-critical NC functions is dependent on high-speed NCK I/O interfaces or the facility to rapidly address particular PLC I/Os (see Section 2.5).

For this reason, the SINUMERIK 840D, 840Di and FM-NC systems are designed to permit

a) the use of digital and analog NCK inputs and outputs (see Chapter 3).

b) direct addressing of particular PLC I/Os (see Section 2.5).

The hardware inputs and outputs can be read and written via system variables in the part program or synchronized actions.

Via the PLC interface, both the signal states of the digital I/Os and the values of the external analog I/Os can be changed by the PLC user program according to the application.

840D hardware
On the SINUMERIK 840D on-board NCU there are 4 digital NCK inputs (inputs 1 to 4) and 4 digital NCK outputs (outputs 1 to 4).

The digital on-board inputs and outputs are stored in the first address byte. With the NCK outputs, the remaining signals of this byte (NCK outputs 5 to 8) can be used via the PLC interface (digital NCK outputs without hardware).

Using the “NCU terminal block” that can be coupled to the drive bus, it is possible to connect further digital NCK inputs/outputs and analog NCK inputs/outputs (hereafter called external NCK I/Os). The “NCU terminal block” is used as a carrier module for up to eight DP compact plug-in modules. Up to two “NCU terminal blocks” can be connected per NCU.

The maximum degree of expansion of the external NCK I/Os is:

- 32 digital NCK inputs (digital inputs 9 to 40)
- 32 digital NCK outputs (digital outputs 9 to 40)
- 8 analog NCK inputs (analog inputs 1 to 8)
- 8 analog NCK outputs (analog outputs 1 to 8)

For further information about the hardware specification see:

References: /PHD/, SINUMERIK 840D NCU Manual
The SINUMERIK FM-NC has no digital on-board inputs or outputs.

The I/O signals of the 1st address byte (NCK inputs 1 to 8 or NCK outputs 1 to 8) can be used via the PLC interface (digital NCK inputs/outputs without hardware).

Connection of external NCK I/Os:
Using the local P bus, it is possible to connect I/O modules of the standard I/Os of the AS300.

If FM servo is used as the 5th axis on the local P bus, it is possible to use the four digital inputs and outputs on the module as external NCK I/Os. The four remaining signals of this byte can be used via the PLC interface (digital NCK inputs/outputs without hardware).

For further information about the hardware specification see:

References: /PHF/, SINUMERIK FM-NC, NCU Manual

Digital inputs/outputs are provided for the SINUMERIK 840Di via the MCI Board Extension module. The following connections are available:

- 2 handwheels
- 2 sensors
- 4 digital inputs/outputs

Note
The MCI Board Extension module is an option for the SINUMERIK 840Di. The PIN assignment of the cable distribution interface (X121) matches the cable distributor assignment on the SINUMERIK 840D.

Analog and digital inputs/outputs can be operated on the SINUMERIK 840Di by means of SIMATIC S7 bus interface and signal boards linked via the PROFIBUS-DP.

Up to 16 bytes for digital input signals and analog input values plus a total of 16 bytes for digital output signals and analog output values can be addressed directly by the part program. These bytes must be taken into account when the PLC is configured. They must be programmed consecutively. They are processed directly by the PLC operating system. As a result, the signal transfer time between the NC and PLC I/O modules is of a magnitude of 0.5 ms.

Caution
The output bytes specified for the NCK may not be write-accessed by the PLC user program as the access operations between the NCK and PLC would be uncoordinated.
2.1 General functionality

For further details, see 2.5.

Comparator inputs

In addition to the digital and analog NCK inputs, 16 internal comparator inputs (comparator input bytes 1 and 2) are also available.

The signal state of a comparator input is formed by comparing an analog input signal with a threshold value in a setting data.

See Section 2.6 for additional information.

Number

The number of addressable digital NCK input/output bytes and analog inputs/outputs must be programmed by means of general machine data.

<table>
<thead>
<tr>
<th>Machine data (SMN_ ...)</th>
<th>Number of active ...</th>
<th>Max. number</th>
</tr>
</thead>
<tbody>
<tr>
<td>FASTIO_DIG_NUM_INPUTS</td>
<td>Digital NCK input bytes</td>
<td>5</td>
</tr>
<tr>
<td>FASTIO_DIG_NUM_OUTPUTS</td>
<td>Digital NCK output bytes</td>
<td>5</td>
</tr>
<tr>
<td>FASTIO_ANA_NUM_INPUTS</td>
<td>Analog NCK inputs</td>
<td>8</td>
</tr>
<tr>
<td>FASTIO_ANA_NUM_OUTPUTS</td>
<td>Analog NCK outputs</td>
<td>8</td>
</tr>
</tbody>
</table>

Note

By definition, the 1st byte is always assigned to the 4 digital I/Os on the MCI Board Extension module on the SINUMERIK 840Di. Even if you have not connected an MCI Board Extension module to the SINUMERIK 840Di, the 1st byte is always assigned to this module.

For this reason, you must enter at least 2 bytes in machine data FASTIO_DIG_NUM... if you want to operate further I/O devices via the PROFIBUS.

Corresponding alarms are generated if the part program addresses inputs/outputs that have not been defined in the above machine data.

These NCK inputs or outputs do not have to actually exist in the hardware. If they do not, the signal states or the binary analog values are set to "zero" in a defined way inside the NCK. The values can be changed by the PLC.
The following general machine data ($MN_{-} ...$) are provided for assigning I/O signal modules or I/O modules to external NCK I/Os:

- MD 10366: HW_ASSIGN_DIG_FASTIN[hw] Hardware assignment for external digital inputs
- MD 10368: HW_ASSIGN_DIG_FASTOUT[hw] Hardware assignment for external digital outputs
- MD10362: HW_ASSIGN_ANA_FASTIN[hw] Hardware assignment for external analog inputs
- MD10364: HW_ASSIGN_ANA_FASTOUT[hw] Hardware assignment for external analog outputs

[hw]: Index for addressing the external digital I/O bytes (0 to 3) or the external analog inputs/outputs (0 to 7)

**Note**
The HW assignment is different on the SINUMERIK 840D, 840Di and FM-NC controls.

The defaults for the assignment of I/Os for the SINUMERIK 840Di via machine data MD 10362 to MD 10368 are as follows:

<table>
<thead>
<tr>
<th>Machine data ($MN_{-} ...$)</th>
<th>Meaning</th>
<th>default</th>
</tr>
</thead>
<tbody>
<tr>
<td>HW_ASSIGN_ANA_FASTIN[0] ...</td>
<td>Assignment for analog input (16-bit access)</td>
<td>050000A0</td>
</tr>
<tr>
<td>HW_ASSIGN_ANA_FASTOUT[0] ...</td>
<td>Assignment for analog output (16-bit access)</td>
<td>050000A0</td>
</tr>
<tr>
<td>HW_ASSIGN_DIG_FASTIN[0] ...</td>
<td>Assignment for digital input (8-bit access)</td>
<td>05000090</td>
</tr>
<tr>
<td>HW_ASSIGN_DIG_FASTOUT[0] ...</td>
<td>Assignment for digital output (8-bit access)</td>
<td>05000090</td>
</tr>
</tbody>
</table>

**Modification to MD for PROFIBUS-DP**
The machine data $MN_{-} HW_ASSIGN_{-} ...$ have been modified for hardware operation on the PROFIBUS-DP of the SINUMERIK 840Di.

The assignment of bytes 1 to 4 has been redefined. The machine data assignments below apply for PROFIBUS-DP operation:

<table>
<thead>
<tr>
<th>Byte</th>
<th>New for PROFIBUS-DP</th>
<th>Previous meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>4th byte</td>
<td>Segment number = 5</td>
<td>Segment number</td>
</tr>
<tr>
<td>3rd byte</td>
<td>Not used = 0</td>
<td>Module number</td>
</tr>
<tr>
<td>2nd byte</td>
<td>Logical high address</td>
<td>Submodule number</td>
</tr>
<tr>
<td>1st byte</td>
<td>Logical low address</td>
<td>Input/output number</td>
</tr>
</tbody>
</table>
Guidelines for machine data $MN\_HW\_ASSIGN\_\ldots$:

- Logical address in 1st and 2nd bytes is specified in hexadecimal format. Example: 050001A2 (Hex) equals logical address 418 (Dec).
- Address 0 is reserved for the PLC and cannot be used as an NC I/O.
- The value 05000000 in MD $MN\_HW\_ASSIGN\_\ldots$ is interpreted as “Slot does not physically exist”. The input is then treated like a simulation input.

System variables

The following table lists the system variables with which NCK I/Os can be read or written directly by the part program.

The number of the NCK input/output is used for addressing.

The following applies to $n$:

- $1 \leq n \leq 8 \cdot MD$ 10350: FASTIO_DIG_NUM_INPUTS
- $1 \leq n \leq 8 \cdot MD$ 10360: FASTIO_DIG_NUM_OUTPUTS
- $1 \leq n \leq MD$ 10300: FASTIO_ANA_NUM_INPUTS
- $1 \leq n \leq MD$ 10310: FASTIO_ANA_NUM_OUTPUTS

<table>
<thead>
<tr>
<th>System variable</th>
<th>Meaning</th>
<th>Range of $[n]$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$A_IN[n]$</td>
<td>Read digital NCK input $[n]$</td>
<td>1 to 3, 9 to 40</td>
</tr>
<tr>

</tr>
</tbody>
</table>

Note

When this system variable is read by the part program, a preprocess stop (STOPRE command) is initiated inside the control.

Value ranges

- $A\_PBB\_OUT(n)$ \(0 \leq x \leq 255\)
- $A\_PBW\_OUT(n)$ \(-32768 \leq x \leq 32767\)

Weighting factor

The weighting factors in the general machine data MD 10320:

FASTIO\_ANA\_INPUT\_WEIGHT[hw] and MD 10330:

FASTIO\_ANA\_OUTPUT\_WEIGHT[hw] allow each individual analog NCK input and output to be adapted to the AD or DA converters of the analog I/O module used.

If the correct weighting factor is set, the value set in system variable $A\_OUTA[n]$ outputs the corresponding voltage value in millivolts at the analog output $[n]$. 
Example for 840D

The analog value range is 10V (maximum modulation);

\[ \text{FASTIO_ANA_OUTPUT_WEIGHT}_{[\text{hw}]} = 10000 \] (standard value for 840D)

\[ A\_\text{OUTA}[1] = 9500 \quad ; \quad 9.5 \text{ V is output at analog NCK output 1} \]

\[ A\_\text{OUTA}[3] = -4120 \quad ; \quad -4.12 \text{ V is output at analog NCK output 3} \]

Application for analog NCK inputs/outputs without hardware:

With weighting factor of 32767, the digitized analog values for part program and PLC accesses are identical. In this way, it is possible to use the associated input or output word for a 1:1 communication between the part program and the PLC.

Assignment to NC functions

Several NC functions are dependent on the functionality of the NCK I/Os. The NCK inputs and/or outputs used for these functions are assigned on a function-specific basis via machine data (e.g. MD 21220: MULTFEED_ASSIGN_FASTIN for "Multiple feedrates in one block "). A byte address must be specified in the machine data for the digital inputs/outputs; the assignment is always made byte by byte.

Clock-synchronous processing

The I/O modules of the external NCK I/Os on the SINUMERIK 840D can be operated in one of the following two modes:

- **Asynchronously**, i.e. the input and output values are made available in cycles set by the terminal block which are asynchronous to the internal NC processing cycles.

- **Synchronously**, i.e. the input values and the output values are provided synchronously with the settable internal NC processing clock frequency.

The processing mode is selected for individual modules by means of general machine data MD 10384: HW_CLOCKED_MODULE_MASK\[tb\].

\[ [tb] = \text{Index for terminal block (0 to 1)} \]

In synchronous processing mode, one of the following clock rates can be selected (general MD 10380: HW_UPDATE_RATE_FASTIO\[tb\]):

- Synchronous inputs/outputs in position control cycles (default setting)
- Synchronous inputs/outputs in interpolation cycles

A lead time set in microseconds can be defined for clocked NCK I/Os in general machine data MD 10382: HW_LEAD_TIME_FASTIO\[tb\]. This makes it possible to consider the conversion time of the ADC for example, so that the digitized input value is available on the cycle.
The defined cycle frequency or delay time applies to all cycle-synchronous I/O modules of the terminal block addressed with [tb].

On the SINUMERIK FM-NC, the I/O modules of the external NCK I/Os **always operate asynchronously**. They are updated in position control cycles.

**Monitoring functions**

The following functional monitors are provided for external I/Os on the SINUMERIK 840D:

- During power-on:
  - Check whether the I/O modules in the terminal blocks match the MD assignments

- During cyclic operation:
  - Sign-of-life monitoring in interpolation cycles
  - Module monitoring in interpolation cycles
  - Temperature monitoring

In the event of a fault, NC ready is cancelled and an alarm is output.

With the SINUMERIK FM-NC, the following function monitoring features check the external I/Os:

- Sign-of-life monitoring in interpolation cycles
- Module monitoring in interpolation cycles

In the event of a fault, NC ready is cancelled.

For further information about monitoring functions see:

**References:**

/PHD/, SINUMERIK 840D, NCU Manual

/PHF/, SINUMERIK FM-NC, NCU Manual

**Response to faults**

The digital and analog NCK outputs are switched to “safe” status (i.e. 0V at output) in the event of faults (e.g. NC ready = 0) in the NCU or power failures.
2.2 Digital inputs/outputs of the NCK

2.2.1 Digital inputs of the NCK

Number

With the general MD 10350: FASTIO_DIG_NUM_INPUTS (number of active digital NCK input bytes) the available digital NCK inputs can be defined (in groups of 8).

Function

The digital NCK inputs allow external signals to be injected which can then be used, for example, to control the workpiece machining program sequence. With the system variable \$A_IN[n]\$, the signal status of the digital input [n] can be scanned directly in the part program.

The signal state at the hardware input can be changed by the PLC user program (see Fig. 2-1).

Disable input

The PLC user program can disable NCK inputs individually by means of interface signal “Disable digital NCK inputs” (DB10, DBB0 or DB122 ...). In this case, they are set to “0” in a defined manner inside the control.

Set input from PLC

The PLC can also apply interface signal “Setting digital NCK inputs on PLC” (DB10, DBB1 or DBB123 ...) to set each digital input to a defined “1” signal state (see Fig. 2-1). As soon as this interface signal is set to “1”, the signal state at the hardware input or the input disable is inactive.

Read actual value

The signal status of the digital NCK inputs is signaled to the PLC (interface signal “Actual value of digital NCK inputs” (DB10, DBB60, DBB186 ...)). The actual value reflects the real state of the signal at the hardware input; the influence of the PLC is therefore ignored in the “actual value” (see Fig. 2-1).

RESET/POWER ON behavior

After POWER ON and reset, the signal level at the input is passed on. If necessary, the PLC user program can disable or set the inputs to “1” in a defined manner as described above.

Applications

The program sequence can be controlled with conditional go-to statements in the part program as a function of the signal status of an external hardware signal.
For example, digital NCK inputs can be used for the following NC functions:

- Delete distance-to-go with positioning axes
- Fast program branching at the end of block
- Programmed read-in disable
- Multiple feedrates in one block

**References:** /FB/, S5, “Synchronized Actions”

The NCK inputs are assigned to the NC functions separately for each function and byte in the machine data. Multiple assignments of inputs are not monitored.

---

**Fig. 2-1** Signal flow for digital NCK inputs
2.2.2 Digital outputs of the NCK

Number
With the general MD 10310: FASTIO_DIG_NUM_OUTPUTS (number of active digital NCK output bytes) the available digital NCK outputs can be defined (in groups of 8).

Function
The digital NCK outputs provide the option of outputting important switching commands at high speed as a function of the program processing status. With the system variable $A_OUT[n]$, the signal status of the digital output [n] can be set or read again directly in the part program.

There are also several ways of changing this set signal state via the PLC (see Fig. 2-2).

Disable output
The PLC user program is capable of disabling the digital NCK outputs individually with interface signal “Disable digital NCK outputs” (DB10, DBB4, DBB130 ...). In this case, the “0” signal is output at the hardware output (see Fig. 2-2).

Overwrite screen form
Every output that can be set by the NC part program can be overwritten from the PLC using the overwrite screen form. Previous NCK values are then lost (see Fig. 2-2).

The following routine has to be carried out to overwrite the NCK value from the PLC:

1. The output in question must be preset with the required signal state at the PLC interface “PLC setting for digital NCK outputs” (DB10, DBB6, DBB132 ...).

2. The setting value becomes the new NCK value for the output (DB10, DBB5, DBB131 ...) when the overwrite screen form is activated (signal transition 0 → 1). This value remains active until the next time the value is programmed (in the PLC or NC part program).

Setting screen form
Furthermore, a PLC setting for each output can determine whether the instantaneous “NCK value” (e.g. as specified by NC part program) or the PLC value specified via the setting screen form (DB10, DBB7, DBB133 ...) should be sent to the hardware output (see Fig. 2-2).

The following routine has to be carried out to define the PLC value:

1. The output in question must be preset with the required signal state at the PLC interface “PLC setting for digital NCK outputs” (DB10, DBB6).

2. The setting screen form must be set to “1” for the output in question.

Unlike the overwrite screen form, the current NCK value is not lost when a value is set in the setting screen form. As soon as the PLC sets “0” in the setting screen form, the NCK value is again active.
2.2 Digital inputs/outputs of the NCK

Note
The same setting value (DB10, DBB6) is used at the PLC interface for the overwrite and setting screen forms. Therefore, an identical output signal state is the result if the signal state is changed simultaneously in the overwrite and setting screen form.

Read setpoint
The instantaneous “NCK value” at the digital outputs can be read by the PLC user program (interface signal “Setpoint of digital NCK outputs” (DB10, DBB64, DBB186 ...)). Please note, however, that this setpoint is unaffected by disabling commands or the setting screen form of the PLC. The setpoint can therefore be different from the actual signal state at the hardware output (see Fig. 2-2).

RESET/end of program
On end of program or RESET, every digital output can be defined as necessary by the PLC user program in the overwrite screen form, setting screen form or disable signal.

POWER ON
After POWER ON, the digital outputs are set to “0” in a defined manner. After POWER ON, this can be overwritten in the PLC user program according to the application using the screen forms described above.

Digital NCK outputs without hardware
If digital NCK outputs defined in MD 10360: FASTIO_DIG_NUM_OUTPUTS are written by the part program but do not exist as hardware, no alarm is output. The NCK value can be read by the PLC (IS “Setpoint ...”)

Applications
This function allows digital hardware outputs to be set instantaneously by bypassing the PLC cycles. Time-critical switching functions can thus be triggered in connection with the machining process and under program control (e.g. on block change).

For example digital NCK outputs are required for the following NC functions:

- Position signals

- Output of the comparator signals (see Section 2.6)

The NCK outputs are assigned to the NC functions separately for each function in machine data. Multiple assignments of outputs are checked during POWER ON and indicated by an alarm.
2.2 Digital inputs/outputs of the NCK

Fig. 2-2 Signal flow for digital NCK outputs
2.3 Connecting and logic operations of fast NCK inputs/outputs

Function

In SW 4 and higher, the fast inputs of the NCK I/Os can be set in the software according to the signal states of the fast outputs.

Overview:

<table>
<thead>
<tr>
<th>Output:</th>
<th>Input:</th>
</tr>
</thead>
<tbody>
<tr>
<td>– Byte</td>
<td>– Byte</td>
</tr>
<tr>
<td>– Bit</td>
<td>– Bit</td>
</tr>
</tbody>
</table>

Alternatives:

1. Connect
2. OR operation
3. AND operation

Connect

The fast input of the NCK I/O is set to the signal state of the assigned fast output.

OR operation

The fast input of the NCK I/O takes the signal state which is given by the OR operation of the output signal with the assigned input signal.

AND operation

The fast input of the NCK I/O takes the signal state which is given by ANDing the output signal with the assigned input signal.

Special cases

- If several output bits are assigned to the same input bit, then the one with the highest MD index becomes effective.
- If inputs or outputs are specified which do not exist or are not activated, then the assignment is ignored without alarm. Checking of the active bytes of the NCK I/Os is performed via the entries in the machine data:
  MD 10350: $MN_FASTIO_DIG_NUM_INPUTS and
  MD 10360: $MN_FASTIO_DIG_NUM_OUTPUTS.
2.3 Connecting and logic operations of fast NCK inputs/outputs

**Defining assignments**

The assignments are specified via machine data:

MD 10361 : $MN\_FASTIO\_DIG\_SHORT\_CIRCUIT[n]$.  
Values from 0 to 9 can be specified for n, therefore up to 10 assignments can be specified.  
The byte and the bit of the output and input are specified in 2 hexadecimal characters respectively. The type of logic operation is specified by entering  
0  for connect  
A  for AND operation  
B...for OR operation  
in bits 12–15 of the input.

<table>
<thead>
<tr>
<th>FASTIO_DIG_SHORT_CIRCUIT[n]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Output</td>
</tr>
<tr>
<td>Bit</td>
</tr>
<tr>
<td>24–31</td>
</tr>
</tbody>
</table>

**Examples**

Connect:  
$MN\_FASTIO\_DIG\_SHORT\_CIRCUIT = '04010302H'$  
Output: bit 4, byte 1, connect to  
input: bit 3, byte 2

AND operation:  
$MN\_FASTIO\_DIG\_SHORT\_CIRCUIT = '0705A201H'$  
Output: bit 7, byte 5 AND operation with  
input: bit 2, byte 1

OR operation:  
$MN\_FASTIO\_DIG\_SHORT\_CIRCUIT = '0103B502H'$  
Output: bit 1, byte 3 OR operation with  
input: bit 5, byte 2
2.4 Analog inputs/outputs of the NCK

2.4.1 Analog inputs of the NCK

Number

With the general MD 10300: FASTIO_ANA_NUM_INPUTS (number of active analog NCK inputs) the available analog NCK inputs can be defined.

Function

The system variable $A_INA[n]$ allows the value at the analog NCK input [n] to be directly accessed in the part program.

The analog value at the hardware input can also be influenced by the PLC user program (see Fig. 2-3).

Disable input

The PLC user program is capable of disabling the analog NCK inputs individually with interface signal "Disable analog NCK inputs" (DB10, DBB146). In this case, they are set to “0” in a defined manner inside the control.

Set input from PLC

The PLC can also specify a value for each analog NCK input by applying the interface signal “Setting screen form of analog NCK inputs” (DB10, DBB147) (see Fig. 2-3). As soon as this interface signal is set to “1”, the value set by the PLC (DB10, DBB148 to 163) becomes active for the analog input. The analog value at the hardware input or the input disable is then inactive.

Read actual value

The interface signal “Actual value of analog input of NCK” (DB10, DBB194 to 209) transfers the analog values that are actually present at the hardware inputs to the PLC. The possible influence of the PLC is therefore ignored in the actual value (see Fig. 2-3).

RESET/POWER ON behavior

After POWER ON and RESET, the analog value at the input is passed on. If necessary, the PLC user program can manipulate the NCK inputs as described above in the PLC user program.

Weighting factor

Using the weighting factor in the general MD 10320: FASTIO_ANA_INPUT_WEIGHT(hw) it is possible to adapt each analog NCK input to the various ADCs for reading in the part program (see Fig. 2-3).

In this machine data it is necessary to enter the value x that is to be read in the part program with the system variable $A_INA[n]$, if the corresponding analog input [n] is set to the maximum value or if the value 32767 is set for this input via the PLC interface. The voltage level at the analog input is then read with the system variable $A_INA[n]$ as a numerical value with the unit millivolts.
2.4 Analog inputs/outputs of the NCK

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
2.4 Analog inputs/outputs of the NCK

Fig. 2-3 Signal flow for analog NCK inputs
2.4.2 Analog outputs of the NCK

With the general MD 10310: FASTIO_ANA_NUM_OUTPUTS (number of active analog NCK outputs) the available analog NCK outputs can be defined.

The system variable $A_OUTA[n]$ allows the value at the analog output $[n]$ to be specified directly in the part program.

Before output to the hardware output, the analog value set by the NCK can be changed by the PLC (see Fig. 2-4).

The PLC user program is capable of disabling the analog NCK outputs individually with interface signal “Disable analog NCK outputs” (DB10, DBB168). In this case, 0 volts is output at the analog output (see Fig. 2-4).

Every NCK analog value set by the NC part program can be overwritten from the PLC using the overwrite screen form. Previous NCK values are then lost (see Fig. 2-4).

The following routine has to be carried out to overwrite the NCK value from the PLC:

1. The output in question must be preset with the required analog value at the PLC interface “PLC setting for analog output n of the NCK” (DB10, DBB170 to 185).
2. The setting value becomes the new NCK value for the analog output (DB10, DBB166) when the overwrite screen form is activated (signal transition 0 -> 1).

This value remains valid until a new value is set for the NCK by the part program, for example.

Furthermore, a PLC setting for each output can determine whether the instantaneous “NCK value” (e.g. as specified by NC part program) or the PLC value specified via the setting screen form (DB10, DBB167) should be sent to the hardware analog output (see Fig. 2-4).

The following routine has to be carried out to define the PLC value:

1. The output in question must be preset with the required analog value at the PLC interface “PLC setting for analog output n of the NCK” (DB10, DBB170 to 185).
2. The setting screen form (DB10, DBB167) must be set to “1” for the output in question.

Unlike the overwrite screen form, the current NCK value is not lost when a value is set in the setting screen form. As soon as the PLC sets “0” in the setting screen form, the NCK value is again active.
Note
The same setting value (DB10, DBB170 to 185) is used at the PLC interface for the overwrite and the setting screen forms.

Read setpoint
The instantaneous NCK value at the analog outputs can be read by the PLC user program (interface signal "setpoint analog output n of NCK" (DB10, DBB210 to 225)). Please note that this setpoint ignores disabling and the setting screen form of the PLC. The setpoint can therefore differ from the real analog value at the hardware output (see Fig. 2-4).

RESET/end of program
On end of program or reset, every analog output can be defined as necessary by the PLC user program in the overwrite screen form, setting screen form or disable signal.

POWER ON
After POWER ON, the analog outputs are set to "0" in a defined manner. After power-on, this can be overwritten in the PLC user program according to the application using the screen forms described above.

Weighting factor
Using the weighting factor in the general MD 10330: FASTIO_ANA_OUTPUT_WEIGHT[hw] it is possible to adapt each analog NCK output to the various DACs for programming in the part program (see Fig. 2-4).
In this machine data it is necessary to enter the value x that is to cause the analog output [n] to be set to the maximum value or the value 32767 to be set for this output in the PLC interface, if $A_OUTA[n] = x$ is programmed. The value set with the system variable $A_OUTA[n]$ then places the corresponding voltage value at the analog output in millivolts.

Binary analog value display
See Section 2.5.1

Special case
Where the part program contains programmed values for NCK analog outputs that have been defined in MD 10310: FASTIO_ANA_NUM_OUTPUTS but do not exist as hardware, no alarm is output. The NCK value can be read by the PLC (IS "Setpoint ...")

Applications
This function allows analog outputs to be set instantaneously by bypassing the PLC cycles.
The analog NCK outputs are used in particular for grinding and laser machines.

Fig. 2-4 Signal flow for analog NCK outputs
2.5 PLC I/Os directly addressable from NC (SW 5 and later)

Introduction
The class of signals and input/output values described below is processed directly and thus significantly faster by the PLC operating system. The signal transfer time between the NC and PLC I/O modules is of a magnitude of 0.5 ms.

<table>
<thead>
<tr>
<th>I/O devices</th>
<th>central (ms)</th>
<th>distributed (ms)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Typical read access</td>
<td>0.5</td>
<td>0.5</td>
</tr>
<tr>
<td>Typical write access</td>
<td>0.5</td>
<td>0.2</td>
</tr>
</tbody>
</table>

There is no provision for control of signals and analog values (disable, set, overwrite) via the PLC basic and user program. Concurrent access between the NCK and PLC is not meaningful and can lead to malfunctions. Values are transferred in the interpolation cycle.

Accessing
The input/output values are accessed using a special set of system variables from the NC part program and synchronized actions.

Preconditions
Direct PLC I/Os can be addressed with:

Table 2-1 Availability

<table>
<thead>
<tr>
<th>NCU HW</th>
<th>Version</th>
<th>PLC–SW</th>
</tr>
</thead>
<tbody>
<tr>
<td>840D, NCU 561.2</td>

</tr>
<tr>
<td>810D</td>
<td>CCU2 with PLC315–2 DP</td>
<td>3.10.13 and later</td>
</tr>
</tbody>
</table>

The SINUMERIK SW version must be 5.2 or later.

Configuring
To allow PLC I/Os to be addressed directly, independent input and output areas, each defined by the logical initial address set in the PLC and length in bytes, must be configured by the following machine data.

MD 10395: PLCIO_LOGIC_ADDRESS_IN Start of input area

MD: 10394: PLCIO_NUM_BYTES_IN Number of input bytes

MD 10397: PLCIO_LOGIC_ADDRESS_OUT Start of output area

MD: 10396: PLCIO_NUM_BYTES_OUT Number of output bytes
The areas defined in the MD must be contiguous, applied consistently in the PLC configuration and assigned to the appropriate I/O units.

### System variables

| $A_{PB\_IN[n]}$ | Read input byte (8 bits) directly from PLC I/O, INT |
| $A_{PB\_W\_IN[n]}$ | Read input word (16 bits) directly from PLC I/O, INT |
| $A_{PB\_D\_IN[n]}$ | Read input double word (32 bits) directly from PLC I/O, INT |
| $A_{PB\_R\_IN[n]}$ | Read input real value (32 bits) directly from PLC I/O, REAL |

$n$ Byte offset within the PLC input area

Data can be read from the part program and synchronized actions with the system variables for Input. Reading from the part program causes a preprocessing stop.

| $A_{PB\_OUT[n]}$ | Write output byte (8 bits) directly to PLC I/O, INT |
| $A_{PB\_W\_OUT[n]}$ | Write output word (16 bits) directly to PLC I/O, INT |
| $A_{PB\_D\_OUT[n]}$ | Write output double word (32 bits) directly to PLC I/O, INT |
| $A_{PB\_R\_OUT[n]}$ | Write output real value (32 bits) directly to PLC I/O, REAL |

$n$ Byte offset within the PLC output area

Data can be written from the part program and synchronized actions with the system variables for Output. The output data can also be read from the part program and synchronized actions. Reading from the part program causes an automatic preprocessing stop (to achieve synchronization with the real time context).

### Memory order

Input double words are stored and must be processed in the memory order of the NCK, i.e. little endian (least significant byte in lower memory address).

### Note

The smallest addressable unit for a direct PLC I/O is the byte. When signals are processed in write operations, all signal bits in the byte must be set as required. Analogously, the relevant signal bits must be suppressed with NC language tools after a byte has been read.

The system variables mentioned above cannot be used to read or write signals of the machine control panel.
Alignment

The input and output areas for direct PLC I/Os must be assigned in increments according to the data type:

- $A_{PBB\_IN\ n}$: every number $<\text{MD} 10394$: PLCIO\_NUM\_BYTES\_IN
- $A_{PBB\_OUT\ n}$: every number $<\text{MD} 10396$: PLCIO\_NUM\_BYTES\_OUT
- $A_{PBW\_IN\ n}$: every even number $<\text{MD} 10394$: PLCIO\_NUM\_BYTES\_IN
- $A_{PBW\_OUT\ n}$: every even number $<\text{MD} 10396$: PLCIO\_NUM\_BYTES\_OUT
- $A_{PBD\_IN\ n}$: $0, 4, 8, ...<\text{MD} 10394$: PLCIO\_NUM\_BYTES\_IN
- $A_{PBD\_OUT\ n}$: $0, 4, 8, ...<\text{MD} 10396$: PLCIO\_NUM\_BYTES\_OUT
- $A_{PBR\_IN\ n}$: $0, 4, 8, ...<\text{MD} 10394$: PLCIO\_NUM\_BYTES\_IN
- $A_{PBR\_OUT\ n}$: $0, 4, 8, ...<\text{MD} 10396$: PLCIO\_NUM\_BYTES\_OUT

Evaluation of analog values

In the case of inputs, the part program reads precisely the values coded by the analog/digital converter on the input module. In the case of outputs, the part program must supply exactly those values which the digital/analog converter on the output module can code into the required output value.
2.5.1 Analog value representation of the analog input and output values of the NCK

Conversion of analog values

The analog values are only processed by the NCU in a digital form.

Analog input modules convert the analog process signal into a digital value.

Analog output modules convert the digital output value into an analog value.

Analog value representation

The digitized analog value is identical for input and output values with the same rating range (e.g. voltage range ±10V DC).

The analog values are coded in the PLC interface as fixed-point numbers (16 bits including sign) in two's complement (see Table 2-2).

Table 2-2 Digital coding of analog values at the PLC interface

<table>
<thead>
<tr>
<th>Resolution</th>
<th>Binary analog value</th>
</tr>
</thead>
<tbody>
<tr>
<td>High byte</td>
<td>15 14 13 12 11 10 9 8</td>
</tr>
<tr>
<td>Low byte</td>
<td>7 6 5 4 3 2 1 0</td>
</tr>
<tr>
<td>Significance of the bits</td>
<td>SG 2^14 2^13 2^12 2^11 2^10 2^9 2^8</td>
</tr>
<tr>
<td></td>
<td>2^7 2^6 2^5 2^4 2^3 2^2 2^1 2^0</td>
</tr>
</tbody>
</table>

Sign

The sign (SG) of the analog value is always in bit 15.

SG is:

"0" → +
"1" → −

Resolution less than 15 bits

The analog value can be finely adjusted depending on the resolution of the digital/analog converter.

If the resolution of the analog module is less than 15 bits, the analog value is entered left-justified. The free less significant places are filled with zeroes.

Table 2-3 shows how the free bit places are filled with zeroes with a 14-bit and a 12-bit analog value.

With a resolution of 14 bits (including sign), the minimum increment is 1.22mV (10V: 8192). In this case, both less significant bits of the analog value (bit0 and bit1) are always 0.

With a resolution of 12 bits (including sign), the increments are 4.8mV (10V: 2048); bits 0 to 3 are always 0.
### Table 2-3 Examples of digital analog value coding

The resolution and the nominal range of the analog input/output modules are to be found in:

**References:**
- /PHD/, SINUMERIK 840D, NCU Manual
- /PHF/, SINUMERIK FM-NC, NCU Manual
- /S7H/, SIMATIC S7, Manual

### Examples

Here are two examples of digital analog value coding for a nominal range of 10V and 14-bit resolution.

**Example 1**

Analog value: 9.5V  
Absolute value (decimal number): 7782  
$= 9.5(V) \times 10(V) \times 8192$

- Absolute value (binary number): 0111 1001 1001 10
- Words (binary number): 0111 1001 1001 1000
- Words (hexadecimal number): 7998

**Example 2**

Analog value: -4.12V  
Absolute value (decimal number): 3375  
$= -4.12(V) \times 10(V) \times 8192$

- Absolute value (binary number): 0011 0100 1011 11
- Two's complement: 1100 1011 0100 01
- Words (binary number): 1100 1011 0100 0100
- Absolute value (hexadecimal number): CB44
2.6 Comparator inputs

Function

2 internal comparator inputs bytes (with 8 comparator inputs each) are available in addition to the digital and analog NCK inputs. The signal status of the comparator inputs is generated on the basis of a comparison between the analog values present at the high-speed analog inputs and high-speed values parameterized in setting data (see Fig. 2-5).

The system variable $A_{INCO}[n]$ allows the signal status (i.e. the result of the comparison) of comparator input $[n]$ to be scanned directly in the part program.

The following applies to index $n$:
- $n = 1$ to $8$ for comparator byte 1
- $n = 9$ to $16$ for comparator byte 2

Terms

In this description, the terms “comparator inputs” (with index $[n]$; range of $n$: 1 to 8 or 9 to 16) and “comparator input bits” (with index $[b]$; range of $b$: 0 to 7) are used.

They are related as follows:
- For $n = 1$ to $8$: Comparator input $n$ is equivalent to comparator input bit $b = n - 1$
- For $n = 9$ to $16$: Comparator input $n$ is equivalent to comparator input bit $b = n - 9$

Example

Comparator input 1 is equivalent to comparator input bit 0.

Assignment of analog inputs

General MD 10530: COMPAR_ASSIGN_ANA_INPUT_1 $[b]$ is set to assign an analog input to input bit $[b]$ of comparator byte 1.

Example

MD 10530: COMPAR_ASSIGN_ANA_INPUT_1[0] = 1
MD 10530: COMPAR_ASSIGN_ANA_INPUT_1[1] = 1
MD 10530: COMPAR_ASSIGN_ANA_INPUT_1[7] = 7
Analog input 1 is assigned to input bits 0 and 1 of comparator byte 1
Analog input 7 is assigned to input bit 7 of comparator byte 1

The assignment for comparator byte 2 must be made analogously in the general MD: 10531 COMPAR_ASSIGN_ANA_INPUT_2 $[b]$. 
Comparator parameterization

General MD 10540: COMPAR_TYPE_1 is used to set the following parameters for each bit (0 to 7) of comparator byte 1:

- Comparison type screen form (bits 0 to 7)
  The type of comparison conditions is defined for each comparator input bit.
  
  Bit = 1: The associated comparator input bit is set to "1" if the analog value is \( \geq \) the threshold value.
  Bit = 0: The associated comparator input bit is set to "0" if the analog value is \( \leq \) the threshold value.

- Output of the comparator input byte via digital NCK outputs (bits 16 to 23)
  The comparator bits can also be output directly via the digital NCK outputs in whole bytes. This requires specification in this byte (bits 16 to 23) of the digital NCK output byte to be used (see general MD: 10540 COMPAR_TYPE_1).

- Inversion screen form for outputting the comparator input byte (bits 24 to 31).
  For every comparator signal it is also possible to define whether the signal state to be output at the digital NCK output is to be inverted or not.
  Bit = 0: The associated comparator input bit is not inverted.
  Bit = 1: The associated comparator input bit is inverted.

Threshold values

The threshold values used for comparisons on comparator byte 1 or 2 must be stored as setting data. For every comparator input bit [b], you must enter a separate threshold value.

MD 41600: COMPAR_THRESHOLD_1[b], threshold values for input bit [b] of comparator byte 1 (b = 0 to 7)

Comparator signals as digital NCK inputs

All NC functions that are processed as a function of digital NCK inputs can also be controlled by the signal states of the comparators. The byte address for comparator byte 1 (HW byte 128) or 2 (HW byte 129) must be entered in the MD associated with the NC function: “Assignment of hardware byte used”.

Example

NC function “Multiple feedrates in one block”.
Setting in channel-specific MD 21220: MULTFEED_ASSIGN_FASTIN = 129.
Now the various feedrates are activated depending on the state of comparator byte 2.
2.6 Comparator inputs

Fig. 2-5  Functional sequence for comparator input byte 1 (or 2)
Supplementary Conditions

Availability of the function “Digital and analog NC inputs/outputs”

Digital and analog CNC inputs/outputs (DI, DO, AI, AO) are available as follows:

- SINUMERIK FM-NC with NCU 570, SW 2 and higher
  16 DI / 16 DO with extension via S7 I/Os

- SINUMERIK 840D with NCU 571, SW 2 and higher
  4 DI / 4 DO (on-board)
  32 DI / 32 DO with extension via NCU terminal block

- SINUMERIK 840D with NCU 572/573, SW 2 and higher
  4 DI / 4 DO (on-board)
  32 DI / 32 DO and 8 AI / AO with extension via NCU terminal block

Analog I/Os for 840Di

The analog I/Os are connected to the SINUMERIK 840Di via the PROFIBUS-DP.
## Data Descriptions (MD, SD)

### 4.1 General machine data

#### FASTIO_ANA_NUM_INPUTS

<table>
<thead>
<tr>
<th>MD number</th>
<th>Description</th>
<th>Default value: 0</th>
<th>Min. input limit: 0</th>
<th>Max. input limit: 8</th>
<th>Changes effective after Power On</th>
<th>Protection level: 2 / 4</th>
<th>Unit: –</th>
<th>Data type: BYTE</th>
<th>Applies from SW version: 2.1</th>
</tr>
</thead>
<tbody>
<tr>
<td>FASTIO_ANA_NUM_INPUTS</td>
<td>Number of active analog NCK inputs</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Significance:**
This machine data defines the number of usable analog NCK inputs on the control. Only these analog NCK inputs can be addressed by the NC part program or assigned by NC functions. If more analog NCK inputs are defined in the machine data than are available in the hardware of the control, the binary analog actual value is set to zero in the control for the inputs that do not exist in the hardware. The NCK value can be altered by the PLC (see Section 2.4.1).

**Note:** CPU computing time on the interpolation level is required for processing the digital and analog NCK I/Os. The number of active NCK I/Os should be limited to the demands of the machine so that the interpolation cycle is not overloaded.

#### FASTIO_ANA_NUM_OUTPUTS

<table>
<thead>
<tr>
<th>MD number</th>
<th>Description</th>
<th>Default value: 0</th>
<th>Min. input limit: 0</th>
<th>Max. input limit: 8</th>
<th>Changes effective after Power On</th>
<th>Protection level: 2 / 4</th>
<th>Unit: –</th>
<th>Data type: BYTE</th>
<th>Applies from SW version: 2.1</th>
</tr>
</thead>
<tbody>
<tr>
<td>FASTIO_ANA_NUM_OUTPUTS</td>
<td>Number of active analog NCK outputs</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Significance:**
This machine data defines the number of usable analog NCK outputs on the control. Only these analog NCK outputs can be addressed by the NC part program or assigned by NC functions. If more analog NCK outputs are defined in the machine data than are available in the hardware of the control, no alarm is triggered. The analog values specified by the part program can be read by the PLC (see Section 2.4.2).

**Note:** CPU computing time on the interpolation level is required for processing the digital and analog NCK I/Os. The number of active NCK I/Os should be limited to the demands of the machine so that the interpolation cycle is not overloaded.
10320

<table>
<thead>
<tr>
<th>10320</th>
<th>FASTIO_ANA_INPUT_WEIGHT [hw]</th>
</tr>
</thead>
<tbody>
<tr>
<td>MD number</td>
<td>Weighting factor for analog NCK inputs [hw]</td>
</tr>
</tbody>
</table>

- **Default value:**
  - 840D: 10 000
  - FM-NC: 11851
- **Min. input limit:** 1
- **Max. input limit:** 10 000 000
- **Changes effective after Power On:**
- **Protection level:** 2 / 4
- **Unit:** –
- **Data type:** DWORD
- **Applies from SW version:** 2.1

**Significance:**

With this MD a weighting factor can be defined for every analog NCK input [n] with which adaptation to the various A/D converters (depending on the I/O module used; different modules can be used on the FM-NC) is possible.

[hw] = Index (0–7) for addressing the external analog inputs

The value x must be entered in this machine data which is then to be read in the part program with the command x = $A_INA[n] if the corresponding analog input [n] is set to the maximum value or if the value +32767 is set for this input via the PLC interface.

The value read from the AD converter or PLC interface must be multiplied by the factor (FASTIO_ANA_INPUT_WEIGHT / 32767) before it can be read by system variable $A_INA[n] in the part program (see Fig. 2-3).

An internal value of ± 32767 is generated if the maximum input voltage is applied at the AD converter.

Use of the weighting factor for “Analog NCK inputs without hardware”: With a weighting factor of 32767 the values defined by the part program and the PLC are identical (1:1 communication between part program and PLC). This is of advantage when the analog NCK inputs/outputs are used purely as PLC inputs/outputs without analog hardware.

**Note:** The comparator threshold values MD 41600: COMPAR_THRESHOLD_1 or MD 41601: COMPAR_THRESHOLD_2 are also scaled to FASTIO_ANA_INPUT_WEIGHT for comparison purposes according to their analog input assignment.

**Application**

**Example 1:** Measuring range of the analog input module: 0 to 2V (standard range)

(FM-NC) Maximum value: 2370mV (corresponds to 32767)

FASTIO_ANA_INPUT_WEIGHT[0] = 2370

An analog value of 2V is represented as the digitized value +27648 (6C00H) at IS "Actual value ..." (DB10, DBB199...) and read in the part program with the system variable $A_INA[n] = 2000.

**Example 2:** Measuring range of the analog input module: 0 to 10V (standard range)

(FM-NC) Maximum value: 11851mV (corresponds to 32767)

FASTIO_ANA_INPUT_WEIGHT[1] = 11851

An analog value of 10V is the digitized value 27648 (= PLC value); 10000 is read with $A_INA[n].

**Related to ....**

IS "Setpoint from the PLC for the analog NCK inputs" (DB10, DBB148–163)

IS "Setpoint from the PLC for the analog NCK outputs" (DB10, DBB170–185)

IS "Setpoint of analog NCK outputs" (DB10, DBB210–225)
10330

<table>
<thead>
<tr>
<th>MD number</th>
<th>FASTIO_ANA_OUTPUT_WEIGHT [hw]</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Weighting factor for analog NCK outputs [hw]</td>
</tr>
</tbody>
</table>

**Default value:**
- 840D: 10000
- FM-NC: 11852

**Min. input limit:** 1
**Max. input limit:** 10 000 000

**Changes effective after Power On:**
**Protection level:** 2 / 4
**Unit:** –

**Data type:** DWORD
**Applies from SW version:** 2.1

**Significance:** With this MD a weighting factor can be defined for every analog NCK output [n] with which adaptation to the various DA converters (depending on the I/O module used) is possible.

**[hw]** = Index (0–7) for addressing the external analog outputs

The value x must be entered in this machine data which is to cause the analog output [n] to be set to the maximum value or set the value +32767 for this output in the PLC interface if $A\_OUTA[n] = x$ is programmed in the part program. An internal value of ±32767 therefore represents the maximum output voltage at the DA converter.

Use of the weighting factor for “Analog NCK outputs without hardware”: With a weighting factor of 32767 the values defined by the part program and the PLC are identical (1:1 communication between part program and PLC). This is of advantage when the analog NCK outputs are used purely as PLC outputs without analog hardware.

**Application**

Example (FM-NC):

- Output range of the analog output module: 0 to 10V
- Maximum value (overrange): 11852mV (corresponds to 32767)
- $\text{FASTIO\_ANA\_OUTPUT\_WEIGHT}[0] = 11852$

If $A\_OUTA[n] = 10000$ is programmed, +27648 (6C00H) is represented at IS “Setpoint...” (DB10, DBB210...) and output at analog output +10V.

Example (840D):

- Output range of the analog output module: 0 to 10V
- Maximum value: 10 000mV (corresponds to 32767)
- FASTIO_ANA_OUTPUT_WEIGHT[0] = 10000

If $A\_OUTA[n] = 10000$ is programmed, +32767 (i.e., 7FFF) is represented at IS “Setpoint...” (DB10, DBB210...) and set at analog output +10V.

**Related to....**
- IS “Setpoint from the PLC for the analog NCK inputs” (DB10, DBB148–163)
- IS “Setpoint from the PLC for the analog NCK outputs” (DB10, DBB170–185)
- IS “Setpoint of analog NCK outputs” (DB10, DBB210–225)
## 4.1 General machine data

### 10350
**FASTIO_DIG_NUM_INPUTS**

<table>
<thead>
<tr>
<th>MD number</th>
<th>FASTIO_DIG_NUM_INPUTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of active digital NCK input bytes</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Default value: 1</th>
<th>Min. input limit: 0</th>
<th>Max. input limit: 5</th>

</tbody>
</table>

<table>
<thead>
<tr>
<th>Data type: BYTE</th>
<th>Applies from SW version: 2.1</th>
</tr>
</thead>
</table>

**Significance:**
The number of bytes of the digital NCK outputs that can be used on the control are defined in this machine data.

These digital NCK outputs can be set directly by the part program. The PLC is able to
- set the digital outputs with IS "Disable the digital NCK outputs" to "0" in a defined way.
- alter the NCK value with IS "Overwrite screen form for digital NCK outputs".
- specify a PLC value with IS "Setting screen form for digital NCK outputs".
- alter the NCK value with IS "Overwrite screen form for digital NCK outputs".

If more digital NCK outputs are defined in the machine data than are available in the hardware of the control, no alarm is triggered. The signal states specified by the part program can be read by the PLC.

See Section 2.2.2 for a more detailed description.

**Special cases, errors, ......**
Digital NCK outputs 5 to 8 can only be processed by the PLC (no hardware outputs).

**Related to ....**

<td>on FM-NC:</td>
<td>02070004</td>
<td></td>
</tr>
</tbody>
</table>

**Significance:**  
The following 4 bytes define the assignment between the external analog NCK inputs and the hardware.

**Applies to 840D/810D and FM-NC:**

1st byte: I/O no.
2nd byte: Submodule no.
3rd byte: Module no.
4th byte: Segment no.

**Applies to 840Di:**

1st byte: Logical low address
2nd byte: Logical high address
3rd byte: Not used (00)
4th byte: Segment no. for PROFIBUS-DP (05)

Array length = maximum number of analog inputs on NCK is set in MD10300.

As soon as value 0 is entered in byte 3 (module no.) external I/Os are no longer processed by the control. A simulated input is defined.

The hardware assignment is different on the SINUMERIK 840D/810D, 840Di and FM-NC controls.

The individual bytes are explained under MD: 10366: HW_ASSIGN_DIG_FASTIN.

**[hw]** = Index (0 – 7) for addressing the external analog inputs

**Related to ....**

#### Changes effective after Power On: Protection level: 2 / 4

<table>
<thead>
<tr>
<th>Unit: Hex</th>
</tr>
</thead>
</table>

#### Data type: DWORD

#### Applies from SW version: 2.1

#### Significance:

The following 4 bytes define the assignment between the external digital NCK I/Os and the hardware.

- **Applies to 840D/810D and FM-NC:**
  - 1st byte: I/O no.
  - 2nd byte: Submodule no.
  - 3rd byte: Module no.
  - 4th byte: Segment no.

- **Applies to 840Di:**
  - 1st byte: Logical low address
  - 2nd byte: Logical high address
  - 3rd byte: Not used (00)
  - 4th byte: Segment no. for PROFIBUS-DP (05)

Array length = maximum number of digital input bytes on NCK is set in MD10350.

As soon as value 0 is entered in byte 3 (module no.), the input byte concerned is not processed by the control. A simulated input is defined.

The hardware assignment is different on the SINUMERIK 840D, 840Di and FM-NC.

#### 840D/810D:

- I/O no.: Number of the I/O byte on the DP compact module (range: 1 to 2; always 1 for analog inputs/outputs)
- Submodule no.: Submodule slot on the terminal block into which the DP compact module is slotted (range: 1 to 8)
- Module no.: Number of the logical slot into which the terminal block with the external I/Os is slotted.
  - The assignment of the logical slot to a physical slot is made with MD 13010: DRIVE_LOGIC_NR (logical drive number). Each module occupies a physical slot. The first 6 slots on the 810D are permanently assigned.
- Segment no.: for 840/810D always 1 (identifier for 611D bus)

**Example:**

<table>
<thead>
<tr>
<th>HW.Assign_DIGITAL_FASTIN[3]</th>
<th>01 04 03 02</th>
</tr>
</thead>
<tbody>
<tr>
<td>1st byte: 02 = 2. input byte of a 16 bit input module</td>
<td></td>
</tr>
<tr>
<td>2nd byte: 03 = Input module slotted into slot 2 of the terminal block</td>
<td></td>
</tr>
<tr>
<td>3rd byte: 04 = Terminal block slotted into logical drive number 4</td>
<td></td>
</tr>
<tr>
<td>4th byte: 01 = Identifier for 611D bus</td>
<td></td>
</tr>
</tbody>
</table>
### 10366 HW_ASSIGN_DIG_FASTIN [hw]

**MD number**: Hardware assignment of external digital NCK inputs

<table>
<thead>
<tr>
<th>Significance:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>FM-NC:</strong></td>
</tr>
<tr>
<td>I/O no.: Number of the input byte on the signal module (range depends on the I/O group: 1 to 4)</td>
</tr>
<tr>
<td>Submodule no.: Of no relevance for FM-NC (this byte must be preset with 01 in a defined way)</td>
</tr>
<tr>
<td>Module no.: Number of the physical slot on the local P bus (Range 1 to 7)</td>
</tr>
<tr>
<td>Note: The FM-NC is slot 0; the physical slots for the digital and analog I/Os are located to the left of this.</td>
</tr>
<tr>
<td>Segment no.: Always 2 for FM-NC (identifier for local P bus)</td>
</tr>
</tbody>
</table>

**Example:** HW_ASSIGN_DIGITAL_FASTIN[3] = 02 04 00 02
- 1st byte: 02 = input byte for a 16 bit digital input module
- 2nd byte: 00 = Not relevant
- 3rd byte: 04 = Input module slotted into logical slot 4
- 4th byte: 02 = Identifier for local P bus

[hw] = Index (0 to 3) for addressing the external digital input byte

**Related to...**

</tr>
<tr>
<td>Changes effective after Power On</td>
<td>Protection level: 2 / 4</td>
</tr>
<tr>
<td>Data type: BYTE</td>
<td>Applies from SW version: 2.1</td>
</tr>
</tbody>
</table>

**Significance:**
With this machine data, the cycle frequency for the clock-synchronous input and output of the external NCK I/Os is selected (840D only).

The cycle time applies to all I/O modules on a terminal block that are operated in synchronism with the clock (MD 10384: HW_CLOCKED_MODULE_MASK[tb]=1).

The selection can be made from the following cycle frequencies:

Value = 1: Synchronous input/outputs in hardware cycles (not in SW 2)
(SYSCLOCK_CYCLE_TIME / SYSCLOCK_SAMPL_TIME_RATIO)

2: Synchronous input/outputs in position control cycles (default setting)
(MD: POSCTR_SYSCLOCK_TIME_RATIO)

3: Synchronous inputs/outputs in interpolation cycles
(MD: IPO_SYSCLOCK_TIME_RATIO)

**Note on index [tb] (tb = 0 to 1):**
Index [tb] identifies the connected NCU terminal blocks in ascending order of the defined logical module numbers (parameterization with MD: DRIVE_LOGIC_NR “logical drive number”).

**Example:** An additional 2 terminal blocks which are parameterized with the logical drive number 6 and 7 are connected to the drive bus.

The following assignments are made for the terminal blocks in the control:
- HW.UPDATE_RATE_FASTIO[0] parameterizes terminal block 1 with no. 6
- HW.UPDATE_RATE_FASTIO[1] parameterizes terminal block 2 with no. 7

This assignment applies analogously to:
MD 10380: HW.UPDATE_RATE_FASTIO[tb] and
MD 10384: HW_CLOCKED_MODULE_MASK [tb]

For more detailed information see
**References:** /FB/, G2, “ Velocities, Setpoint/Actual Value Systems, Closed-Loop Control”

**Note:** Please consider the hardware response times of the external I/O modules used.

Lead time for clock-synchronous external NCK I/Os

<table>
<thead>
<tr>
<th>Default value: 0</th>
<th>Min. input limit: 0</th>
<th>Max. input limit: plus</th>
<th>Changes effective after Power On</th>
<th>Protection level: 2 / 4</th>
<th>Unit: ms</th>
<th>Data type: DWORD</th>
<th>Applies from SW version: 2.1</th>
</tr>
</thead>
</table>

Significance:
A lead time can be defined for digital and analog NCK I/Os (MD 10384: HW_CLOCKED_MODULE_MASK = 1) operated in synchronism with the clock.

The input signal is stored this length of time before the defined cycle. The output signal is sent to the hardware this same length of time before the defined cycle.

With NCK inputs, for example, this makes it possible to consider the hardware-determined conversion time of the AD converter so that the digitized analog value is available on the cycle.

If the value set in this machine data exceeds the fixed cycle time (MD 10380: HW_UPDATE_RATIO_FASTIO), it is limited internally to the largest possible offset (i.e. to the parameterized cycle time).

The lead time applies to all NCK inputs/outputs of the terminal block addressed with index [tb] which are operated in synchronism with the clock.

**Note** on index [tb] see MD 10380: HW_UPDATE_RATE_FASTIO.

MD irrelevant for ......  
SINUMERIK FM-NC

Clock-synchronous processing of external NCK I/Os

<table>
<thead>
<tr>
<th>Default value: 00</th>
<th>Min. input limit: 00</th>
<th>Max. input limit: FF</th>
<th>Changes effective after Power On</th>
<th>Protection level: 2 / 4</th>
<th>Unit: Hex</th>
<th>Data type: BYTE</th>
<th>Applies from SW version: 2.1</th>
</tr>
</thead>
</table>

Significance:
With SINUMERIK 840D, the I/O modules of the external NCK I/Os can be operated in the following way:
- **Asynchronously**, i.e. the input and output values are made available in cycles set by the terminal block which are asynchronous to the internal NC processing cycles.
- **Synchronously**, i.e. the input and output values are made available synchronously to a settable internal NC processing cycle.

The mode of operation can be set via a bit screen form (bits 0 to 7) for each individual I/O module of the terminal block address with index [n] (bit 0 for I/O module on slot 1 ... bit 7 for I/O module on slot 8).

The bits have the following meaning:
- Bit n = 0: I/O module on slot n+1 is operated **asynchronously**
- Bit n = 1: I/O module on slot n+1 is operated **synchronously**

The value is of no significance for unassigned slots of the terminal block.

Example: HW_CLOCKED_MODULE_MASK[0] = 30  (bit screen form: 0011 0000)
The I/O modules of terminal block 1 on slots 6 and 5 are operated in synchronism with the clock.

**Note**: Digital NCK inputs/outputs are generally always operated asynchronously. When analog NCK inputs/outputs are used in closed control loops, values often have to be read in and out in synchronism with the clock.

**Notes**:
- on index [tb] see MD 10380: HW_UPDATE_RATE_FASTIO.
- Module 6FC5211-0AA10-0AA0 can only operate synchronously.

MD irrelevant for ......  
SINUMERIK FM-NC (always operated asynchronously)

### 10530 COMPAR_ASSIGN_ANA_INPUT_1[b]

<table>
<thead>
<tr>
<th>MD number</th>
<th>Hardware assignment of analog inputs for comparator byte 1 (or 2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default value: 0</td>
<td>Min. input limit: 0</td>
</tr>
<tr>
<td>Changes effective after Power On</td>
<td>Protection level: 2 / 4</td>
</tr>
<tr>
<td>Data type: BYTE</td>
<td>Applies from SW version: 2.1</td>
</tr>
</tbody>
</table>

#### Significance:
With this MD, the analog inputs 1 to 8 are assigned to a bit number of comparator byte 1 or 2. This input bit of the comparator is set to “1” if the comparison between the applied analog value and the associated threshold value (MD 41600: COMPAR_THRESHOLD_1 or MD 41601: COMPAR_THRESHOLD_2) verifies that the condition parameterized in MD 10540: COMPAR_TYPE_1 or MD 10541: COMPAR_TYPE_2 is fulfilled.

An analog input can be assigned several input bits. The following generally applies for comparator byte 1:

\[
\text{COMPAR_ASSIGN_ANA_INPUT_1[b]} = \text{n}
\]

with index b = number of comparator input bit (0 to 7) and with index n = number of analog input (1 to 8)

**Example:**

- COMPAR_ASSIGN_ANA_INPUT_1[0] = 1
- COMPAR_ASSIGN_ANA_INPUT_1[1] = 2
- COMPAR_ASSIGN_ANA_INPUT_1[2] = 1
- COMPAR_ASSIGN_ANA_INPUT_1[3] = 3
- COMPAR_ASSIGN_ANA_INPUT_1[4] = 3
- COMPAR_ASSIGN_ANA_INPUT_1[5] = 1
- COMPAR_ASSIGN_ANA_INPUT_1[6] = 1
- COMPAR_ASSIGN_ANA_INPUT_1[7] = 1

Analogue input 1 affects input bit 0, 2, 5, 6 and 7 of comparator byte 1.
Analogue input 2 affects input bit 1 of comparator byte 1.
Analogue input 3 affects input bit 3 and 4 of comparator byte 1.

The same also applies to comparator byte 2 with respect to COMPAR_ASSIGN_ANA_INPUT_2[b].

See Section 2.6 for a more detailed description.

**Related to:**
- MD 10531: COMPAR_ASSIGN_ANA_INPUT_2[b]
- MD 10540: COMPAR_TYPE_1
- MD 10541: COMPAR_TYPE_2
### 4.2 General setting data

#### 10540
10541
**MD number**

<table>
<thead>
<tr>
<th>Parameterization for comparator byte 1 or 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default value: 0</td>
</tr>
<tr>
<td>Changes effective after Power On</td>
</tr>
<tr>
<td>Data type: DWORD</td>
</tr>
</tbody>
</table>

**Significance:**
The following parameters can be set with COMPAR_TYPE_1 for the individual input bits (0 to 7) of comparator byte 1:

- **Bits 0 to 7:** Type of comparison screen form (for comparator input bit 0 to 7)
  - Bit = 1: Input bit = 1 when analog value ≥ threshold value
  - Bit = 0: Input bit = 1 when analog value < threshold value

(Threshold value set with MD 41600: COMPAR_THRESHOLD_1 or MD 41601: COMPAR_THRESHOLD_2)

- **Bits 8 to 15:** Not assigned (to be set to 0 in a defined way)
- **Bits 16 to 23:** Assignment of a hardware output byte for the output of the comparator states (stating byte address)
  - Byte = 0: No output via digital NCK outputs
  - Byte = 1: Output via digital on-board NCK outputs (1 to 4)
  - Byte = 2: Output via external digital NCK outputs 9 to 16
  - Byte = 3: Output via external digital NCK outputs 17 to 24
  - Byte = 4: Output via external digital NCK outputs 25 to 32
  - Byte = 5: Output via external digital NCK outputs 33 to 40

- **Bits 24 to 31:** Inversion screen form for the output of comparator states (bit 0 to 7)
  - Bit = 0: Input bit is not inverted
  - Bit = 1: Input bit is inverted

The same also applies to comparator byte 2 with COMPAR_TYPE_2.

See Section 2.6 for additional information.

</tr>
<tr>
<td>Data type: DOUBLE</td>
<td>Applies from SW version: 2.1</td>
</tr>
</tbody>
</table>

**Significance:**
COMPAR_THRESHOLD_1[b] defines the threshold values for the individual input bits[b] of comparator byte 1.

The same also applies to comparator byte 2 with COMPAR_THRESHOLD_2[b].

Index [b]: Bits 0–7

See Section 2.6 for a more detailed description.

5.1 NC-specific signals

In Sections 5.1.1 and 5.1.3, only those signals are listed in the overview that are actually described below. A complete list of all signals is to be found in:

Comments
#) Bits 4 to 7 of the digital NCK outputs can be processed by the PLC even though there are no equivalent hardware I/Os. These bits can therefore be used additionally for data exchange between the NCK and PLC.
§) On the SINUMERIK 840D digital inputs and outputs 1 to 4 of the NCK are on-board inputs and outputs. No hardware I/Os are available for bits 0 to 3 on the FM-NC. These can be processed by the PLC as described under #).

### Overwrite screen form for digital NCK outputs

<table>
<thead>
<tr>
<th>DB10</th>
<th>DBB5, 131, 135, 139, 143</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data block</td>
<td></td>
</tr>
</tbody>
</table>

**Signal(s) to NC (PLC → NC)**

**Edge evaluation:** no

**Signal(s) updated:** cyclically

**Signal(s) valid from SW vers.:** 1.1

**Signal state 1 or signal transition 0 → 1**

On signal transition 0 → 1 the previous NCK value is overwritten by the setting value (IS “Setting value from PLC for digital NCK outputs”). The previous NCK value, which, for example, was directly set by the part program, is lost.

The signal status defined by the setting value forms the new NCK value.

For more information please see Section 2.2.2

**Signal state 0 or signal transition 1 → 0**

As the interface signal is only evaluated by the NCK on signal transition 0 → 1 it must be reset to “0” again by the PLC user program in the next PLC cycle.

**Special cases, errors, ......**

Note: The PLC interface for the setting value (DB10, DBB6) is used both by the overwrite screen form (for signal transition 0 → 1) and the setting screen form (for signal state 1). Simultaneous activation of the two screen forms via the PLC user program must be avoided.

**Related to ....**

### Setting by PLC of digital NCK outputs

<table>
<thead>
<tr>
<th>DB10</th>
<th>DBB6, 132, 136, 140, 144</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data block</td>
<td></td>
</tr>
</tbody>
</table>

**Signal(s) to NC (PLC → NC)**

**Edge evaluation:** no

**Signal(s) updated:** cyclically

**Signal(s) valid from SW vers.:** 1.1

**Signal state 1 or signal transition 0 → 1**

The signal status for the digital hardware output can be changed by the PLC with the setting value. There are two possibilities:

1. With the ‘overwrite screen form’:
   On signal transition 0 → 1 the PLC overwrites the previous ‘NCK value’ with the ‘setting value’. This is the new ‘NCK setting value’.

2. With the ‘setting screen form’:
   On signal state 1, the ‘PLC value’ is activated. The value used is the ‘setting value’.

On setting value “1”, signal level 1 is output at the hardware output; on “0”, 0 signal level is output. The corresponding voltage values are given in

**References:**
/PHF/, SINUMERIK FM-NC NCU Manual
/PHD/, SINUMERIK 840D NCU Manual

For more information please see Section 2.2.2

**Signal state 0 or signal transition 1 → 0**

As the interface signal is only evaluated by the NCK on signal transition 0 → 1 it must be reset to “0” again by the PLC user program in the next PLC cycle.

**Special cases, errors, ......**

Note: The PLC interface for the setting value (DB10, DBB6) is used both by the overwrite screen form (for signal transition 0 → 1) and the setting screen form (for signal state 1). Simultaneous activation of the two screen forms via the PLC user program must be avoided.

#### Setting value from PLC for analog NCK inputs

<table>
<thead>
<tr>
<th>Data block</th>
<th>Setting value from PLC for analog NCK inputs</th>
<th>Signal(s) to NC (PLC → NC)</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Edge evaluation: no</th>
<th>Signal(s) updated: cyclically</th>
<th>Signal(s) valid from SW vers.: 2.1</th>
</tr>
</thead>
</table>

- **Signal state 1 or signal transition 0 ——> 1**

  With this setting value a defined analog value can be set by the PLC. With IS "Setting screen form of analog NCK inputs", the PLC selects whether the analog value at the hardware input or the setting value from the PLC is to be used as the enabled analog value.

  - The setting value from the PLC becomes active as soon as IS "Setting screen form" is set to "1".
  - The setting value from the PLC is specified as a fixed point number (16 bit value including sign) in 2's complement (see Section 2.5.1).
  - For more information please see Section 2.4.1.

  Related to ....

  - IS "Disable analog NCK inputs" (DB10, DBB146)
  - IS "Setting screen form of analog NCK inputs" (DB10, DBB147)
  - IS "Actual value of analog NCK inputs" (DB10, DBB199 to 209)
  - MD 10300: FASTIO_ANA_NUM_INPUTS

### DB10 DBB166

#### Overwrite screen form of analog NCK outputs

<table>
<thead>
<tr>
<th>Data block</th>
<th>Overwrite screen form of analog NCK outputs</th>
<th>Signal(s) to NC (PLC → NC)</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Edge evaluation: no</th>
<th>Signal(s) updated: cyclically</th>
<th>Signal(s) valid from SW vers.: 2.1</th>
</tr>
</thead>
</table>

- **Signal state 1 or signal transition 0 ——> 1**

  On signal transition 0 ——> 1, the previous NCK value is overwritten by the setting value (IS "Setting value from PLC for analog NCK outputs"). The previous NCK value which, for example, was directly set by the part program, is lost.

  The analog value specified by the PLC setting value forms the new NCK value.

  - For more information please see Section 2.4.2.

- **Signal state 0 or signal transition 1 ——> 0**

  As the interface signal is only evaluated by the NCK on signal transition 0 ——> 1 it must be reset to "0" again by the PLC user program in the next PLC cycle.

  Special cases, errors, ..... Note: The PLC interface for the setting value is used both by the overwrite screen form (on signal transition 0 ——> 1) and the setting screen form (signal state 1). Simultaneous activation of the two screen forms must be avoided via the PLC user program.

  Related to ....

<th>Edge evaluation: no</th>
<th>Signal(s) updated: cyclically</th>
<th>Signal(s) valid from SW vers.: 2.1</th>
</tr>
</thead>
</table>

- **Signal state 1 or signal transition 0 ——> 1**

  Instead of the NCK value, the PLC value is output at the analog hardware output. The PLC value must first be stored in IS "Setting value from PLC for the analog NCK outputs".

  The current NCK value is not lost.

  - For more information please see Section 2.4.2.

- **Signal state 0 or signal transition 1 ——> 0**

  The NCK value is output at the analog hardware output.

</tbody>
</table>

**Comments**

- #) Bits 4 to 7 of the digital inputs and NCK outputs can be processed by the PLC although no equivalent hardware I/Os exist. These bits can therefore be used additionally for data exchange between the NCK and PLC.
- §) On the SINUMERIK 840D digital inputs and outputs 1 to 4 of the NCK are on-board inputs and outputs. No hardware I/Os are available for bits 0 to 3 on the FM-NC. These can be processed by the PLC as described under #).

### 5.1.4 Description of signals from NC to PLC (DB10)

#### DB10

<table>
<thead>
<tr>
<th>Data block</th>
<th>Signal(s) to PLC (NC → PLC)</th>
</tr>
</thead>
<tbody>
<tr>
<td>186–189</td>
<td>Signal(s) updated: cyclically</td>
</tr>
<tr>
<td></td>
<td>Signal(s) valid from SW vers.: 2.1</td>
</tr>
</tbody>
</table>

**Actual value for digital NCK inputs**

- **Signal state 1 or signal transition 0 ———> 1**
  - Signal level 1 is active at the digital hardware input of the NCK.

- **Signal state 0 or signal transition 1 ———> 0**
  - Signal level 0 is active at the digital hardware input of the NCK.

**Special cases, errors, ......**

- The influence of IS “Disable digital NCK inputs” is ignored for the actual value.

**Related to ....**

- IS “Disable digital NCK inputs” (DB10, DBB0)
- MD 10350: FASTIO_DIG_NUM_INPUTS

#### DB864

<table>
<thead>
<tr>
<th>Data block</th>
<th>Signal(s) to PLC (NC → PLC)</th>
</tr>
</thead>
<tbody>
<tr>
<td>190–193</td>
<td>Signal(s) updated: cyclically</td>
</tr>
<tr>
<td></td>
<td>Signal(s) valid from SW vers.: 2.1</td>
</tr>
</tbody>
</table>

**Setpoint for digital NCK outputs**

- **Signal state 1 or signal transition 0 ———> 1**
  - The NCK value for the digital output currently set (setpoint) is "1".

- **Signal state 0 or signal transition 1 ———> 0**
  - The NCK value for the digital output currently set (setpoint) is "0".

**Signal irrelevant for......**

- This setpoint is only output to the hardware output under the following conditions:
  1. Output is not disabled (IS “Disable digital NCK outputs”)
  2. PLC has switched to the NCK value (IS “Setting screen form for digital NCK inputs”)

- As soon as these conditions are fulfilled, the setpoint of the digital output corresponds to the ‘actual value’.

**Related to ....**

- IS “Disable digital NCK outputs” (DB10, DBB4)
- IS “Overwrite screen form of the digital NCK outputs” (DB10, DBB5)
- IS “Setting value from PLC for the digital NCK outputs” (DB10, DBB6)

1.1 Topology of distributed system configurations

Properties

Rotary indexing machines, multi-spindle turning machines and complex NC production centers have all or some of the following features:

- More than one NCU owing to large number of axes and channels
- Large dimensions and spatial separation make several control units (MMC operator panels and MCP machine control panels) a necessity.
- Modular machine concept, e.g. through distributed switching cabinets

SW 5 offers a flexible general solution for these applications.

Specification of the software version

The software versions specified in this documentation refer to the SINUMERIK 840D control; the parallel software version for the SINUMERIK 810D control (if the function is released, see /BU/, Catalog NC 60.1) is not specified explicitly.

The following applies:

Table 1-1 Equivalent software versions

<table>

1.1 Topology of distributed system configurations

Fig. 1-1  Topology of distributed system configurations

*) The term PLC–PLC communication refers either to
  – PLC–PLC cross-communication (Master, slave C.) or
  – PLC local I/Os.

The two areas highlighted in the topology display above identify two communications functions to be examined separately in terms of configuration and utilization.

**M : N**

* *(m MMC : n NCU)*

Assignment of several MMC, MCP control units (M) to several NCUs (N).

- Bus addresses, bus type
- Properties of the MMC
  - Main control panel/secondary control panel
- Dynamic switchover from MMCs/MCPs to other NCUs

For a detailed description of these operations, please refer to Chapter 2.
The functions for the NCU link are based on additional communication between the NCUs in the interpolation cycle. The NCU link allows:

- Subordination of a physical axis to several different NCUs
- Interpolation across the NCUs
- An increase in the number of usable axes for an NCU grouping
- An increase in the number of channels for an NCU grouping
- Provision of axis data and signals on the NCU to which a non-local axis is temporarily assigned
- User communication via the NCU grouping by means of link variables

For more information about this topic, please refer to Chapters 1 and 2.

Communication between the master computers and control units is described in

References: /FBR/, SINCOM Computer Link

DP Master, DP Slave, DP–DP coupler, cross-communication via PBK

The buses illustrated in the above topology diagram are specially designed for their transmission tasks. The following communication specifications are shown in the next figure:

- Number of bus nodes
- Baud rate
- Synchronization
1.1 Topology of distributed system configurations

Fig. 1-2 Bus properties

7-layer model structure

Communication takes place on the following protocol layers:

The NCU link and DP can operate faster because they are assigned directly to layer 2.
1.2 Several operator panels and NCUs with control unit management (option)

Introduction

The plant configurations must be highly flexible for complex machines such as rotary indexing machines, multi-spindle machines and complex NC production centers. Often they need

- Several (m) control units (MMC and MCP) owing to large dimensions of machine and physical separation of operator stations,
- Several (n) NCUs owing to large number of axes and channels.

Limitation

The following subsection describes the additional functionality of Software Version 5. These functions are available only in connection with the Control Unit Management function.

The standard functionality applies to all SW versions without the option. However different performance grades depending on SW version must also be taken into account; these are described in Chapter 3.

The standard functionality is described in the following subsection.

While the standard functionality supports only certain restricted combinations of MMCs and NCUs, the control unit management option provides a flexible, universal solution for satisfying the requirements above.

1.2.1 System properties

M:N concept

The M:N concept is represented diagrammatically in Fig. 1-1 “Topology”:

Several control units (MMCs and/or MCPs) are connected to several NCUs via a bus system. As the number of components is variable, they are given the indexes m and n; hence the name M:N concept.

This concept allows the user to connect any control units to any NCUs in the system (within the limits imposed by the hardware) via the bus and to switch them over as and when required.

NCU link

NCU link is an additional direct connection between the NCUs, enabling fast communication (see Sections 1.4 and 2.4).
New features

The features of SW 5 including the control unit management option are as follows:

- Independent connection of MMC and MCP
- Two independent MMC-PLC interfaces on each NCU for two autonomous MMC connections
  - MMC and MCP can be switched over together, or the MMC on its own,
  - MMC states:
    - online/active: operation and monitoring
    - online/passive: A window is displayed with header and alarm line and a message indicating "passive" state
    - offline
- Different bus systems (MPI/OPI) between MMC/MCP and NCUs (changes only take effect after power-up)
- MMC function as server / as Main secondary operator panel
- A combination of both fixed MMCs and switchable MMCs can be connected.
- Suppression mechanism (priority-controlled) if more than two MMCs are competing for an NCU connection
- Up to 32 bus nodes (MMCs, MCPs and/or NCUs, see Fig. 1-2)
- PLC controls the switchover process (control unit switchover to toolbox, directory PSP_PROG\m_zu_n.zip)
- Configuration file NETNAMES.INI with new parameters.

Supplementary conditions

At any one time

- a max. of two MMCs can be online on one NCU,
- only one of them can be in an active state.

1.2.2 Hardware

Operator panel

The OP030, OP031 or OP032 operator panels feature a slimline screen, softkeys, a keyboard, interfaces and a power supply. In addition, an MMC 100.2/102 or 103 computer module is attached to OP031/32.

Machine control panel

The machine control panel (MCP) incorporates a keyboard, rotary button pad and interfaces.
1.2 Several operator panels and NCUs with control unit management (option)

**Difference between OP030 and OP031/32**

OP030 and OP031/32 differ in their assignment options to an NCU:

- The OP030 can only have a fixed assignment to one NCU. It can be used as a second operator panel for this NCU. The addresses of the connected partners can be set for this purpose.
- The OP031/32 can have an active assignment to another NCU via MMC 100.2/102/103 operation.

**References**

The operator interfaces are described in the Operator’s Guides for the relevant operator panels.

- /BA/, Operator’s Guide
- /FBO/, OP030 Operator Interface
- /BH/, Operator Components Manual

**Buses**

The control units (MMCs and/or MCPs) and NCUs are connected by means of the

- MPI bus (Multi-Point Interface, 187.5 kbaud) or
- OPI bus (Operator Panel Interface, 1.5 Mbaud).

It is possible to combine different bus systems within one installation.

**Address assignments**

Bus nodes each have a unique address on the bus. The NCU uses

- a common address for the NC and PLC on the OPI,
- two separate addresses (for NC and PLC) on the MPI interface. The following applies:
  - SW 3.1 and higher: PLC address can be re-configured with STEP7. The default address on the MPI for the PLC is “2”.
  - SW 3.2 and higher: As regards the addresses on the MPI interface, the following applies to a PLC-CPU 315: NC address = PLC address + 1
  - SW 3.5 and higher: As regards the addresses on the MPI interface, the following applies to a PLC-CPU 314: NC address = PLC address + 1

**Default settings for OPI**

Address 0 (MMC) is reserved and 13 (NCK) set as the default in the factory state; these addresses should not be assigned to nodes in M:N systems.

- Address 0 is reserved for PG diagnostics,
- Address 13 is preset for service/installation and start-up. The address can be reconfigured through operation on the MMC. Reserved the address for NCU replacement if possible.

**Defaults for MPI**

- Address 2 for PLC
- Address 3 for NCU

**Number of active MMCs on 1 NCU**

A maximum of two MMCs (incl. COROS OPs) can be continually connected actively to an NCU. MMCs on the OPI or MPI count in the same way.
1.2 Several operator panels and NCUs with control unit management (option)

**Number of MCPs/HHUs on 1 NCU**
As standard, two MCPs and one HHU can be connected to the OPI or MPI interface. The handheld programming unit (HPU) counts as an MMC and an MCP.

---

**Note**
The MPI/MCP network rules outlined in the “SINUMERIK 840D Installation Guide” Section 3.1 must be applied.

In particular, an M:N installation must be connected up by means of cables fitted with terminating resistors (identifiable by switch with which these are switched in and out).

---

1.2.3 Functions

**Defining properties**
The flexible M:N concept makes it possible to extensively modify the properties of the control units.

The assignment of the MMC properties can either be
- static or
- dynamic.

**Static properties**
Static system properties are configured in file NETNAMES.INI (see paragraph below). They become effective at power-up and cannot be changed during the runtime:
- Assignment of bus nodes – bus system
- Combination of different bus systems (OPI, MPI)
- Assignment of MMCs – NCUs (which MMCs can monitor which NCUs)
- MCP changeover
- Suppression priorities at changeover (see below)
- Utilization properties (see Chapter 2 “Properties of MMCs”):
  - Operator panel is the alarm/ data management server
  - The control panel is main or secondary control panel

**Dynamic properties**
The dynamic properties can be changed during runtime.

The states:
1.2 Several operator panels and NCUs with control unit management (option)

<table>
<thead>
<tr>

</tr>
<tr>
<td></td>
<td></td>
<td>“passive” state</td>
</tr>
</tbody>
</table>

Control unit switchover is **enabled**. Control unit switchover is **disabled**.

**Operating the M:N function**

The M:N function is operated via the “Channel menu” option.

The channel menu is selected via the “Switch over channel” key. The horizontal softkeys are used for selecting a channel group (MMC 100.2: max. 8, MMC 102/103: max. 24 channel groups); up to eight connections to channels in different NCUs can be set up in one channel group.

The “Channel menu” screen displays all current connections and the associated symbol names.

**Note**

In the case of errors during power-up (for example, link setup fails), see Chapter 2 (Power-up).

**Suppression strategy**

If two MMCs are online on one NCU, and a third MMC would like to go online, then the latter can “suppress” one of the two active MMCs. Communication is then interrupted between this MMC and the NCU.

The algorithm responsible for this suppression is driven by priorities configured in the file NETNAMES.INI (see paragraph 2.1.8 “Suppression”).

**1.2.4 Configurability**

When the M:N system powers up, it must be aware of the existing control units, NCUs and communications links and their properties.

**NETNAMES.INI**

All this information is contained in the configuration file NETNAMES.INI which is configured before power-up.

This present description is mainly intended to provide the necessary knowledge for correctly setting up this configuration file for the M:N concept.
This means that

- the hardware configuration is displayed,
- the properties of the components are defined, and
- the desired switchovers/assignments are possible.
1.3 Several operator panels and NCUs, standard functionality

The following applies to all M:N applications in which the control unit management option is not implemented. The level of performance is also dependent on SW version.

1.3.1 System properties

**SW 3.1 and higher**
- Two MCPs and one HHU can be connected to the MPI or OPI.
- The handheld programming unit (HPU) counts as an MMC and an MCP.
- One of the panels must be an OP030.

**SW 3.2 and higher**
- The configurations “One operator panel and up to three NCUs” are available.
- The necessary configuration in the NC for the connection of MCPs/HHUs is made with the basic PLC routine (see Description of Functions, P3: Basic PLC program).
- Address must be specified in the case of data exchange between PLCs via Profibus DP (PLC-CPU 315 only) or for global data (double addressing).
- The following applies to PLC-CPU 315: NC address = PLC address + 1

**SW 3.5 and higher**
- The configurations “One operator panel and up to four NCUs” and one MMC locally in each case are available.

1.3.2 Hardware

**Buses**
- The connection between MMC 100 or MMC 102/103 (or other operator panel CPUs) and NCUs is made via
  - MPI bus (Multi-Point Interface, 187.5 kbaud) and/or
  - OPI (Operator Panel Interface, 1.5 Mbaud).
- The buses can be used to link \( m \) MMCs and \( n \) NCU/PLC units.

**Up to SW 3.1**
- The machine control panel (MCP) must always be connected to connector X101 (OPI) on the NCU.

**SW 3.2 and higher**
- Possibility of installing “Several operator panels and NCUs” on the OPI (X101 on NCU) and the MPI (X122 on NCU).
1.3 Several operator panels and NCUs, standard functionality

When setting up the link via MPI, the PLC-CPU315 must be used if there are several NCUs, as it is possible to set the NC address with this PLC.

Up to SW 4
Number of bus nodes: max. 16

SW 4.1 and higher
Number of bus nodes: max. 32

1.3.3 Functions

SW 3.1 and higher
“Several operator panels and several NCUs” available in the basic version.

SW 3.2 and higher
Configuration in the NC for the connection of MCPs/HHUs is made with the basic PLC routine (see Description of Functions, P3: Basic PLC program).

- Switchover of link to another NCU with the softkey labeled “conn...”:

  A menu is overlaid where you can select the connections conn_1, ... conn_n (declared in NETNAMES.INI) via softkeys.
  The name (name=...) allocated to the connection in NETNAMES.INI is displayed on the softkeys.

  A connection to the new NCU is established by pressing the softkey.

- Changeover behavior on OP030:

  It is not possible to change to another bus node online. The connection contained in NETNAMES.INI is permanently configured.

- Changeover behavior on MMC 100:

  The “Conn...” softkey is only displayed if more than one link is configured in NETNAMES.INI.
  When changing to the new NCU, the existing connection to another NCU is interrupted.

  MMC applications, at the instant of link changeover, must no longer need the link to the previous NCU (e.g. for active data backup via V.24). Otherwise the control will issue a message if the connection is required.

  With regard to the NCU to which the changeover takes place, the MMC behaves as if the system had been restarted. It is positioned in the operating area which is set as the Start operating area.
1.3 Several operator panels and NCUs, standard functionality

- Changeover behavior on MMC 102/103:
The “Conn...” softkey is displayed only if the m to n function is activated on the control.
“m to n” is activated in menu “Start-up/MMC/Operator panel”. Connections remain established with any changeover and the applications which have used these connections remain active. After the changeover, the MMC is in the same operating area with respect to the new NCU as it was previously with respect to another NCU.

- Possible faults
The NCU with which the connection is to be established can refuse the connection setup. Cause: NCU faulty or the NCU cannot operate with an additional MMC at this point.
The number of MMCs that an NCU can set up a connection with at any one time is configured in MD 10134 (MM_NUM_MMC_UNITS = number of MMC communications partners possible at any one time). OP030 requires one unit, MMC 100 or MMC 102/103 requires two units.

- Alarms, messages

<table>
<thead>
<tr>
<th>MMC 100, OP030</th>
<th>MMC 102/103</th>
</tr>
</thead>
<tbody>
<tr>
<td>It is only possible to output the alarms of the NCU with which a connection is currently established.</td>
<td>The alarms and messages of all connected NCUs can be processed simultaneously.</td>
</tr>
</tbody>
</table>

- Alarm text management

<table>
<thead>
<tr>
<th>MMC 100, OP030</th>
<th>MMC 102/103</th>
</tr>
</thead>
<tbody>
<tr>
<td>Only one version of the alarm texts can be stored on the operator component. The standard alarm texts are stored once in the same formulation for all NCUs. The possible alarms for all connected NCUs must be stored in the one possible area for user alarms.</td>
<td>It is not possible to set up user alarm texts that apply specifically to the NCU (MMC only manages one alarm text file, SW 3.4 MMC 102/103).</td>
</tr>
</tbody>
</table>

- Connection check (MMC 100, MMC 102/103)
The address of a connected NCU (on OPI bus only) can be altered in the “Connections/Service” menu.
The new NCU address is stored on the NCU.
The softkey labeled “Service” is only displayed if the password for “Protection level Service” has been entered.
When the function for changing the address is started up, a direct connection between the MMC and the relevant NCU must always be established to ensure that the address is not programmed more than once on the bus.
1.3 Several operator panels and NCUs, standard functionality

Note
When the NCU (service case) is replaced, or there is a backup battery failure, the address settings are lost.

A general reset on the NCU does not delete the NCU address. The address can only be changed via an MMC. For display of the current connection, an unambiguous channel name should be assigned in MD 20000: CHAN_NAME (channel name).

SW 3.2 – 3.x
Operation of the M : N function

- MMC 102/103
  Select menu "Start-up/MMC/operator panel and choose between
  M : N (parameters for the MMC are stored in file NETNAMES.INI) and
  1 : 1 (addresses can be specified via the MMC).

- MMC 100
  The NETNAMES.INI file must be adapted by means of the application tool. The data are then transferred to the MMC.

SW 3.5 and higher
NC can exchange data with the PLC-CPU 314.

SW 4 and higher
The M:N function is operated via the "channel menu option".
Precondition: Configuration of the NETNAMES.INI file (see /IAD/, Installation & Start-up Guide 840D, section on MMC).
The channel menu is selected via the "Switch over channel" key. The horizontal softkeys are used for selecting a channel group (MMC 100/100.2: max. 8, MMC 102/103: max. 24 channel groups); up to eight connections to channels in different NCUs can be set up in one channel group. The "Channel menu" screen displays all current connections and the associated symbol names.

Note
In the case of errors during power-up (for example, link setup fails), see Chapter 2 (Power-up).
### 1.3.4 Configurability

**SW 3.1 and higher**

2 MMCs : 1 NCU

The option of creating a link between two operator panels and one NCU has been implemented in SW 3.1, as the following diagram illustrates. In this case, there is a fixed assignment between the MCP and the NCU.

![Diagram of operator panels and NCU configuration](image)

**Fig. 1-4** Example configuration for SW 3.1 (m:n corresponds to 2:1)

The operator panels, NCU and machine control panel are all either connected to the OPI bus or the MPI bus. Regarding these components, the network must be **homogeneous**. In SW 3.1, only OP030 may be used as the second operator panel.

The configuration in the diagram would allow, for example, a high-performance operator panel with MMC 100 or MMC 102/103 to be fitted on the front panel of a large machine tool and an OP030 operator panel to be installed in the vicinity of secondary units (or on the rear panel of the machine).

**Characteristics**

When operating two operator panels in the configuration illustrated above, the user will observe the following system operating characteristics:

1. For the NCU, there is no difference whether the input is from the MMC or OP030 operator panels.
2. Each control unit can visualize selected displays independently of the other unit.
3. Spontaneous events such as alarms are displayed on both control units.
4. The protection level set on one MMC will also apply to the second MMC.
5. The system does not provide for any further coordination between the operator panels.

If the user applies the standard configuration shown in the diagram, then no further special settings are required.
1.3 Several operator panels and NCUs, standard functionality

**SW 3.2 and higher**

**1 MMC : 3 NCUs**

In SW 3.2 and higher, it is possible to link one operator panel and up to three NCUs (see Fig. 1-5). In this case, the MCP has a fixed assignment to the relevant NCU.

**Fig. 1-5** Example configuration for SW 3.2 (m:n corresponds to 1:3)

It is possible to operate several NCUs from one MMC (several autonomous machines or one large machine with several NCUs). At any given time, only one preselected NCU is connected with the MMC for operating sequences. The MMC 100 is provided with one connection only for alarms, whereas the MMC 102/103 is connected to all NCUs for alarms.

**Characteristics**

The operating characteristics when several NCUs are linked to one MMC are as follows:

1. **NCU operation:**
   - The user must select the NCU to be operated by means of a softkey.
   - The operator display in the "Connection" operating area displays the name of the connection and the NCU to which the MMC is currently linked.

2. **MMC 100:**
   - No application should be active on the connection which is interrupted by the changeover to another NCU (Example: data backup via V.24).
   - System message "V.24 active" is output if an attempt is made to change over the link when an application is active.
   - For the newly established connection, the MMC is positioned in the preset Start operating area (as with MMC restart).

3. **MMC 102/103:**
   - When a link has been set up with another NCU, the last selected operating area (on the previous NCU) is immediately available for the new NCU.

4. **PLC-CPU:**
   - **SW 3.2 and higher**
     - If the MPI bus is used (connector X122), the PLC must be a PLC-CPU315 to allow variable addressing for the PLC/NC.
   - **SW 3.5 and higher**
     - The PLC-CPU314 can also be used.
**OEM solution**

As an OEM solution, an MMC 102/103 can be connected via an OPI to up to three NCUs (excluding FM-NC/810D, as it does not have an OPI) as a program and alarm server \((m=1, n=3)\). In addition, a PG can be connected with a start-up tool.

**Note**

With SINUMERIK 810D and FM-NC, local MMCs cannot be implemented due to restricted resources.

---

**Characteristics**

The following characteristics are typical of the OEM solution sketched in the above Fig.:

1. **NCU operation:**
   The user must select the NCU to be operated by means of a softkey. The operator screen displays the name of the connection and NCU with which the MMC is currently linked.

2. **MMC 100**
   can only be connected to a local NCU.

3. **MMC 102/103:**
   When a link has been set up with another NCU, the last selected operating area (on the previous NCU) is immediately available for the new NCU.
In addition to the options described above for SW 3.5 and higher, it is also possible to create a link between an operator panel (central MMC) and up to four NCUs, as illustrated in the following diagram. The MCP and the local MMC are permanently assigned to the respective NCU. A second MMC can be connected to the OPI.

![Diagram](image-url)

Fig. 1-7 Example configuration for SW 3.5 (m:n corresponds to 1:4)

It is possible to operate several NCUs from one MMC (several autonomous machines or one large machine with several NCUs). At any given time, only one preselected NCU is connected with the MMC for operating sequences. The MMC 100 is provided with one connection only for alarms, whereas the MMC 102/103 is connected to all NCUs for alarms.

**Note**

With SINUMERIK 810D and FM-NC, local MMCs cannot be implemented due to restricted resources.

**Documentation required**

1.4 NCU link

The NCU link, the link between several NCU units of an installation, is used in distributed system configurations.

### Introduction

NCU link

With high axis/channel requirements, for example, with rotary indexing machines and multi-spindle machines, the computing capacity can exceed the configuration possibilities and storage area offered by one single NCU. Several NCUs interconnected with an NCU link module provide a scalable solution which fully meets the requirements of this type of machine tools. The NCU link module offers fast NCU-NCU communication based on a synchronized 12 MB PROFIBUS interface.

---

**Note**

NCU link is available in conjunction with MMC 103.

---

1.4.1 Types of distributed machines

#### Machine characteristics

Rotary indexing machines/multi-spindle machines have the following characteristics:

- Global, cross-station units (not assigned to one station):
  - Drum/rotary switching axis and
  - Units that go from station (position) to station (position) such as with rotary indexing machines:
    - the rotary axis of the workpiece clamping for multi-face machining operations
    - spindle, quill

- Station-related (position-related), fixed-location units:
  - Slides, milling/drilling units used on the part that is changed from station to station for a machining task.

#### Applications

Rotary indexing machines (RVM) and multi-spindle machines (MS) are used as highly productive machines in the medium and large batch production. Their main advantage is that many machining steps can be performed on the workpiece in one clamp.

#### NCU assignments

According to the configuration of the RVM/MS, the many axes of these machines are assigned to different NCUs. (For example, one NCU for each machining unit or group of machining units). The global units are assigned to a separate NCU or distributed accordingly.
Initial position, status after each machining step

Rotation of drum/rotary table (MTR machine axis) by one position, status prior to each machining step

Fig. 1-8 Sectional diagram of a drum changeover
When advancing the rotary table with RVM or the drum with MS, the axis holding the workpiece moves to the next machining unit.

The axis holding the workpiece is now assigned to the machining unit's channel. This is on another channel in the example, but need not be.

As the above diagram "Drum changeover" shows, machine axis MS1, which is physically controlled by NCU1, is brought into position/station2 through rotation of the drum/rotary table. To ensure that a coordinated machining operation between the slide and spindle can now take place in position/station2, the commands for spindle MS1 are transferred in this position by means of link communication. Spindles MS1, MS2, ... are link axes.

Physical axes can only be subordinate to the motion control of one NCU channel at any one time. However, the motion control initiative for an axis can be assigned to different NCU channels in succession.

**Solutions**

To make a physical axis available to several different NCUs, the Link Axis property has been introduced. See Sections 1.4.2 and 2.5. In the diagram above, MS1 becomes the link axis from the point of view of NCU2 (bottom diagram) after it has been turned to position/station2.

For variable assignment of channel axes to machine axes according to axis groups, the configuration concept axis container has been made available. See Sections 1.4.3 and 2.6.

All link axes which are moved to the next position/station by a particular drum/rotary table must be managed in the same axis container.

**1.4.2 Link axes**

- Link axes
  - Definition:
    - A link axis is an axis
    - whose drive control and position control are subordinate to another NCU or
    - which is the local axis of the NCU concerned, but can be addressed by another NCU.
  - The software option link axis must be installed.

- Coordination
  - The alternate use of a physical axis by several NCUs is dependent on all the relevant NCUs being aware of the status and data of the particular axis and on their ability to coordinate use of the axis.

- Interpolation
  - Local axes and link axes can be interpolated together through motion control by means of one NCU.
1.4 NCU link

- Hardware
  - The NCUs involved in alternate use of axes across NCU limits must be equipped with a link module. The NCU link module offers fast NCU-to-NCU communication based on a synchronized 12-Mbaud Profibus interface.

  References: /PHD/, Configuring Guide NCU 571–573.2

The following description provides the information required to configure, program and coordinate the distributed machines shown in the drawing.

For details please see Section 2.5.

1.4.3 Flexible configuration

Introduction

On rotary indexing machines/multi-spindle machines, the work-holding axes move from one machining unit to the next. As the machining units are under different NCU channels, it is necessary for the axes holding the workpiece to be dynamically reassigned to the appropriate NCU channel in the event of a station/position change. Axis containers are provided for this purpose.

Only one workpiece clamping axis/spindle is active at a time on the local machining unit. The axis container provides the possible connections to all clamping axes/spindles, of which exactly one is activated for the machining unit.

The following can be assigned via the axis container:

- local axes and/or
- link axes

Switching between the available axes defined in an axis container works by cyclical shifting (rotation) of the entries in the axis container.

The modification can be triggered by the part program.

Validity range

Axis containers with link axes are a NCU-cross device (NCU-global) that is coordinated via the control.

It is also possible to have axis containers that are only used for managing local axes.

For details about axis containers, please refer to Section 2.6.
1.4.4 User communication across the NCUs

**Definition**

- Link variables
  - Every NCU connected by means of a link module can address uniformly accessible **global link variables** for all connected NCUs. Link variables can be programmed in the same way as **system variables**. In general, these variables are defined and documented by the machine manufacturer.
  - Applications for link variables:
    - Global machine states
    - Workpiece clamping open/closed
    - ...
  - Data volume comparatively small
  - Transmission rate very high because information relevant to main run is available for exchange.
  - These system variables can be accessed from the **part program** and from **synchronized actions**. You can configure the size of the memory area for global system variables.
  - All connected NCUs require one interpolation cycle before they can consistently read a new value in a global system variable.

For more information about the global system variables, please refer to 2.7.

![Communication overview](image)

**Note**

On installations without an NCU link, the link variables can also be used NCU-locally as an additional means of cross-channel communication. In this case, there is no interpolation cycle between write and read.

Notes
Detailed Description

2.1 Several operator panels and NCUs with control unit management option

The following chapter provides a detailed description of the preparations and implementation of the operating steps for the M:N concept.

Procedure

1. A number of different configurations are possible with the components of the existing system.
   The user selects one of these options to meet his individual requirements:
   - On the hardware side: by interconnecting components via bus systems
   - On the software side: by configuring static properties using configuration file NETNAMES.INI (see following paragraphs).
     These static properties are made operative during power-up and cannot be altered once the system is running.
   - Control unit switchover function in the PLCs of the relevant NCUs. The PLC control unit switchover function comprises several blocks. These implement the following tasks:
     - Check of switchover conditions
     - Prioritized suppression
     - Switchover
   The PLC SW “Control unit switchover” is supplied as part of the toolbox and can be parameterized if necessary. See Section 2.1.14.
   The option can be used only in PLCs with basic program version 05.03.01 or later.

2. Dynamic properties (such as online/offline states) can be changed when the system is running within the limits specified by the NETNAMES.INI file.
2.1 Several operator panels and NCUs with control unit management option

2.1.1 Hardware structure

As described in Chapter 1, a complex system can consist of M (several) control units and n (several) NCUs.

The diagram below illustrates a typical complex system:

Fig. 2-1 Topology of distributed system configurations

*) PLC–PLC communication refers either to
   – PLC–PLC cross-communication (master/slave comm.) or
   – PLC-local I/O.

The hardware components are connected to one another via the bus (MPI and/or OPI). The relationships between the bus nodes (identification, properties, assignment and switchover) are software-controlled.
2.1 Several operator panels and NCUs with control unit management option

2.1.2 Properties

**Client identification**

The assignment between bus nodes and the bus system is static and cannot be changed once the system is running. It is configured once in file NETNAMES.INI.

The client identification (CLIENT_IDENT) is composed of bus type and MMC bus address; the MMC uses it when logging on to an NCU to establish an online connection.

**Properties**

The MMCs in an M:N installation have the following properties:

<table>
<thead>
<tr>
<th>Server</th>
<th>Control panel</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maintains a constant 1:N connection</td>
<td>Can be switched to the different NCUs and maintains a constant 1:1 connection (only one at any one time!). Operator can operate and monitor. Connection is set up when the MMC goes online, and is disconnected when it goes offline.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Alarm server (MMC 103)</th>
<th>Data management server (MMC 103)</th>
<th>Main control panel</th>
<th>Secondary control panel</th>
</tr>
</thead>
<tbody>
<tr>
<td>Receives the alarms from all NCUs in an M:N installation. From its side, a constant 1:N connection is maintained. The process “Receive alarms” is always active and runs in the background.</td>
<td>Establishes all connections configured for it in NETNAMES.INI during power-up and maintains a constant 1:N connection. Can receive, manage and distribute data within the framework of the job list concept.</td>
<td>Example: Main control panel for rotary index machines can be connected to all machining stations.</td>
<td>Example: Secondary control panel for rotary index machines can only be connected to one of two adjacent machining stations.</td>
</tr>
<tr>
<td>Cannot be suppressed (see Section 2.1.8)</td>
<td>Cannot be suppressed.</td>
<td>Cannot be suppressed.</td>
<td>Can be suppressed by the main or secondary control panel.</td>
</tr>
</tbody>
</table>

**Distribution of properties among the MMC types:**

<table>
<thead>
<tr>
<th>Property</th>
<th>MMC 102/103</th>
<th>MMC 100.2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server</td>
<td>x</td>
<td></td>
</tr>
<tr>
<td>Main control panel</td>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>Secondary control panel</td>
<td>x</td>
<td>x</td>
</tr>
</tbody>
</table>

**MMC is both server and main control panel at the same time**

As a server, the MMC maintains constant 1:N connections; as a main control panel it has a switchable 1:1 connection.

If, as a control panel, the MMC is switched to another NCU, it occupies the same connection which it already has as a server. A new connection is not established.
2.1 Several operator panels and NCUs with control unit management option

**Permissible MMC combinations in an installation**

If there is a server (alarm/data management server) in an M:N installation, it is a main control panel at the same time.

In an M:N installation, there can only be one MMC with the following properties:
- Windows MMC (MMC 103) : Server and main control panel
- non-Windows MMC (MMC 100.2) : Main control panel

There can be any number of secondary control panels.

### 2.1.3 Configuration file NETNAMES.INI

**Configuration parameters**

As the hardware components can be freely combined (see the previous paragraph “Hardware structure”), it is necessary to provide the system with information about which components are connected, how they are connected to each other and how they interact.

In particular, it is necessary to regulate the competition among the different MMCs for the limited number of available interfaces (suppression, see 2.1.8).

Each MMC has a configuration file NETNAMES.INI for this purpose; this is where the configuration parameters must be stored.

### 2.1.4 Structure of the configuration file

There is a separate configuration file NETNAMES.INI for each MMC.

It is structured as follows:

I. MMC identification
II. MMC-to-NCU connections
III. Bus identification
IV. MMC description
V. Description of NCU components
VI. Channel data

Fig. 2-2 Structure of the configuration file NETNAMES.INI

In the following tables,
- the components which the user may need to adapt or which can be freely named are shown in *italics*,
- Alternative passwords are specified separated by |.
I. MMC identification
Identification of the MMC. The following is valid for NETNAMES.INI:

<table>
<thead>
<tr>
<th>Element</th>
<th>Explanation</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>[own]</td>
<td>Header</td>
<td>[own]</td>
</tr>
<tr>
<td>owner</td>
<td>Identifier</td>
<td>MMC identification</td>
</tr>
<tr>
<td>MMC identification = 1</td>
<td></td>
<td>owner = MMC_1</td>
</tr>
</tbody>
</table>

II. MMC-to-NCU connections
Configuring the connections between the MMC and the NCUs:

<table>
<thead>
<tr>
<th>Element</th>
<th>Explanation</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>[conn Identifier]</td>
<td>Header</td>
<td>[conn MMC_1]</td>
</tr>
<tr>
<td>conn_i = NCU_ID</td>
<td>Configuring the NCU connection(s)</td>
<td>conn_1 = NCU_1, conn_2 = NCU_2, ... conn_i = NCU_i</td>
</tr>
</tbody>
</table>

III. Bus identification
Defines which bus the MMC is attached to:

<table>
<thead>
<tr>
<th>Element</th>
<th>Explanation</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>[param network]</td>
<td>Header</td>
<td>[param network]</td>
</tr>
<tr>
<td>bus = OPI</td>
<td>Bus designation</td>
<td>bus = OPI</td>
</tr>
</tbody>
</table>

- opi: Operator panel interface with 1.5 Mbaud
- mpi: Multi-point interface with 187.5 kbaud

Note
The baud rate is automatically detected on the MMC 100.2.

IV. MMC description
Characterization of the MMC:

<table>
<thead>
<tr>
<th>Element</th>
<th>Explanation</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>[param Identifier]</td>
<td>Header</td>
<td>[param MMC_1]</td>
</tr>
</tbody>
</table>
| mmc_typ = Type/connection identifier |MMC characteristics (see below) | mmc_typ = 0x40 MMC is server and main operator panel
See below for explanations |
| mmc_bustyp = OPI | Bus the MMC is attached to | mmc_bustyp = OPI |
| mmc_address = Address | MMC_address | mmc_address = 2 |
| mstt_address or mcp_address = address | Address of OPI to be switched simultaneously. If not present, there is no OPI to be switched. | mstt_address = 6 or mcp_address = 6 |
2.1 Several operator panels and NCUs with control unit management option

<table>
<thead>
<tr>
<th>Element</th>
<th>Explanation</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>name = identifier</td>
<td>Any name allocated by the user (optional, max. 32 characters)</td>
<td>name = MMC_LINKS</td>
</tr>
<tr>
<td>start_mode = ONLINE</td>
<td>State after power-up. If ONLINE, link is set up via DEFAULT_channel entry to</td>
<td>start_mode = ONLINE</td>
</tr>
<tr>
<td>OFFLINE</td>
<td>the associated NCU. OFFLINE: No link is set up immediately after power-up.</td>
<td>(during power-up MMC</td>
</tr>
<tr>
<td></td>
<td></td>
<td>is connected online to</td>
</tr>
<tr>
<td></td>
<td></td>
<td>the NCU to which the</td>
</tr>
<tr>
<td></td>
<td></td>
<td>channel is assigned</td>
</tr>
<tr>
<td></td>
<td></td>
<td>via channel data (see</td>
</tr>
<tr>
<td></td>
<td></td>
<td>VI )DEFAULT_logChanGrp, DEFAULT_log_Chan).</td>
</tr>
</tbody>
</table>

Note

Note that the NCU configured via the DEFAULT channel must be the same as the NCU specified under NcddeDefaultMachineName in file MMC.INI.

Explanations to mmc_typ:

mmc_typ contains type and connection identifiers for the MMC and is transferred to the PLC at switching request. mmc_typ is evaluated as priority for the suppression strategy. See Section 2.1.8.

Bit 7 = ––– (reserved)
Bit 6 = TRUE: MMC is server (MMC 103) and cannot be suppressed.
Bit 5 = TRUE: MMC is main control panel.
Bit 4 = TRUE: MMC is secondary control panel.

The user can specify four additional MMC types which the control unit switchover function of the PLC takes into account in its suppression strategy:

Bit 3 = TRUE: OEM_MMC_3
Bit 2 = TRUE: OEM_MMC_2
Bit 1 = TRUE: OEM_MMC_1
Bit 0 = TRUE: OEM_MMC_0

If no mmc_typ is entered in file NETNAMES.INI, then the MMC powers up by the method for standard functionality.

V. Description of the NCU component(s)

You must make a separate entry for each NCU component.

<table>
<thead>
<tr>
<th>Element</th>
<th>Explanation</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>[param NCU_ID]</td>
<td>Header</td>
<td>[param NCU_1]</td>
</tr>
<tr>
<td>name= bel_name</td>
<td>Any name assigned by the user; is output in the alarm line (optional, max. 32 characters)</td>
<td>name= NCU1</td>
</tr>
<tr>
<td>type= NCU_570</td>
<td>NCU type</td>
<td>type= NCU_572</td>
</tr>
<tr>
<td></td>
<td>NCU type</td>
<td>NCU type</td>
</tr>
<tr>
<td></td>
<td>NCU type</td>
<td>NCU type</td>
</tr>
</tbody>
</table>
2.1 Several operator panels and NCUs with control unit management option

<table>
<thead>
<tr>
<th>Element</th>
<th>Explanation</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>nck_address = j</td>
<td>Address of NCU component on the bus: ( j = 1, 2, \ldots, 30 ) *)</td>
<td>nck_address = 14</td>
</tr>
<tr>
<td>plc_address = p</td>
<td>Address of PLC component on the bus: ( p = 1, 2, \ldots, 30 ) *) (only necessary for the MPI bus because ( j ) = ( p ) for the OPI bus)</td>
<td>plc_address = 14</td>
</tr>
</tbody>
</table>

*) With MPI bus:
Since the associated NCU always occupies the next-higher address than the PLC, the PLC address must not be 31. Address 31 can, for example, be assigned to an MMC.

**Note**
If the bus node addresses on the MPI bus are configured in conformance with SIMATIC, the configuring engineer can read out the assigned addresses using a SIMATIC programming device and use them to create the NETNAMES.INI file.

**VI. Channel data**
The control unit switchover option can work only if the control unit knows how channels are assigned to NCUs so that it can set up links between the control unit and NCUs. (Channel menu.)

**Strategy**
The following operations must be performed:
1. Definition of technological channel groups
2. Assignment of channels to groups
3. Assignment of NCUs to channels
4. Definition of power-up link

NCUs are addressed indirectly on the basis of channel group and channel on the control unit. See 2.1.12 Operator interface.

</tbody>
</table>

And so on for all channels in group

Continue with next group and its channels

A complete example of how to configure the channel menu can be found in 6.1.

### 2.1.5 Creating and using a configuration file

**Syntax**

The configuration file must be generated as an ASCII file. The syntax is the same as that used in Windows *.ini files. In particular, the following is applicable:

- Passwords must be typed in small letters.
- Comments can be inserted in the parameter file (limited on the left by ";" and on the right by end of line).
- Blanks may be used as separators at any position except in identifiers and passwords.

**MMC 100.2, OP030**

The NETNAMES.INI file generated on the PC/PG is loaded via the V.24 interface and permanently stored in the FLASH memory of the control units as described in:

**References:** /IK/, Installation Kit.

**MMC 102/103**

The NETNAMES.INI file can be processed directly with an editor (in menu “Start-up/MMC/Editor or DOS_SHELL) on the hard disk of the operator component. The NETNAMES.INI file is stored in the installation directory C:\USER\.

**Sample**

For a sample configuration file, please refer to Chapter 6.
2.1.6 Power up

Defaults
The following defaults are applied if no NETNAMES.INI configuring file is loaded into the MMC 100.2/OP030 or if the latter cannot be interpreted (standard M:N = 1:1):

- The bus type used is automatically determined
- MMC has address 1
- OP030 has address 10
- NCU and PLC both have address 13 for an OPI bus
- NCU has address 3 and PLC address 2 for an MPI bus

With option
If, however, a special NETNAMES.INI file is created, then it must correspond exactly to the actual network on account of the special features described below.

If an M:N-capable MMC fails to set up a link to the NCU during power-up or in the case of a configuring error, the MMC switches over to OFFLINE operating mode. In this MMC mode the operator can switch over to the area application via the Recall key and then to the start-up area.

Compatibility
The use of the above defaults establishes compatibility with earlier software versions for operation of the panel.

Power-up with MMC 100.2
An MMC 100.2 control unit can only set up an active link to the NCU if the configuration in NETNAMES.INI is correct as described in Section “Structure of the configuration file”. MMC 100 and OP030 can power up parallel on one NCU, because as bus nodes they have different addresses.

The OP030 can be used as a second operator panel that has a fixed assignment to an NCU.

If the configured addresses do not match the real addresses (NC/PLC address), the start-up engineer can use the following key sequence to power-up an NCU that is not configured.

Sequence of operations
1. MMC boots on the NCU with bus address 13, if the NETNAMES.INI was not changed (original works settings).
2. File NETNAMES.INI has been altered, message “MMC 100 version xx.xx.xx: waiting for connection ...” is output
   - Press the “1” key, message: “choice: ’1’ = set new start-address, ’ ’ = boot” is displayed
   - Press the “1” key, the bus addresses of all nodes connected to the bus are displayed. The message: “Please try one of the shown addresses or press ’ ’ to reboot ‘1’, ‘ ’, ‘ ’, ‘6’, ‘ ’, ‘ ’, ‘D’, ‘ ’,...” is output.
2.1 Several operator panels and NCUs with control unit management option

- Press “D” key and INPUT
- MMC boots on the NCU with bus address 13 (if an NCU is configured under the address found).

3. Enter new NC address in the Start-up/NC/NC address operating area and confirm with “Yes”.

4. NC reset (new address is only valid after NC reset)

5. Configure connection/channel menu in the NETNAMES.INI file and transfer to the MMC

6. After the NCU addresses have been assigned, the bus can be wired for m:n operation.

Note
You can operate an OP030 and an MMC 100.2 on an interface without assigning parameters (various bus addresses are available in the delivery state).

Power-up with MMC 102/103, standard functionality

The MMC 102/103 can power up even if the link to the NCU cannot be made due to errors in the configuring parameters.
An NCU address can be specified explicitly through the entry of a “1 : 1” connection in the “Start-up/MMC operator panel” menu. When the MMC has powered up again, the communications link between the MMC and NCU/PLC will work properly.

Sequence of operations
1. MMC boots on the NCU with bus address 13, if NETNAMES.INI was not changed (original works settings).
2. NCU bus address was changed, the following alarm is output “120201 name: communication failed”
   - Set the connection to 1:1 in the Start-up/MMC/Operator panel operating area and enter “13” as the NC address
   - Confirm with OK and boot the MMC
3. 6. As on MMC 100.2

Note
In the event of an error, check
- the active bus nodes in the menu
- start-up/NC/NCK addresses (MMC 100.2 and 103),
- start-up/MMC/operator panel (MMC 103).

Power-up with MMC102/103, option

If the control unit switchover option is installed, a configuring problem can be corrected as follows:
1. Select the channel menu with the input key
2. Go to the area switchover screen by pressing Recall
2.1 Several operator panels and NCUs with control unit management option

Documentation required

References: /BH/, Operator Components Manual
            /IAD/, Installation & Start-up Guide
            /FB/ P3, Basic PLC Program

The following is described in these descriptions:
- Creation of MPI/OPI bus link, bus addresses, /IAD
- Bus terminator, /IAD/, /FB/S7/
- Using basic PLC program to connect MCPs, /FB/P3/
- DIP-FIX settings on MCP, /IAD/

2.1.7 MMC switchover

With the M:N concept, you can change the control unit properties and states configured in the NETNAMES.INI file during operation.

For example, the user can
- change MMCs (see Section 2.1.9),
- change MCPs (see Section 2.1.13).

Up to two MMCs can be online at the same time on one NCU. A suppression strategy (see Section 2.1.8) is provided to avoid conflicts when more than two MMCs want to go online on one NCU.

The MMC properties are configured for each MMC in the NETNAMES.INI file. If an MMC wants to go online on an NCU via the switchover protocol, its parameters are passed on to the PLC of the respective NCU. The PLC program Control Unit Switchover evaluates the parameters:
- Check suppression conditions
- Switchover if necessary

2.1.8 Suppression

Up to two MMCs can be online on each NCU. If this is the case, and another MMC would like to go online, it is necessary to ensure that there are no conflicts. This is achieved by means of the suppression algorithm described below.

Procedure
- The PLC sends an offline request to the MMC to be suppressed.
- It returns a positive or negative acknowledgement to the PLC:
  - If it is positive, the MMC is suppressed (see below). It terminates the communication with the NCU and goes into offline mode.
    Any MCP assigned to the MMC is deactivated by the PLC.
  - A negative acknowledgement is output if processes run on the MMC that cannot be interrupted, e.g. operation via V.24 or data transfer between the NCU and MMC.
    In this case the MMC is not suppressed; it remains online on this NCU.
2.1 Several operator panels and NCUs with control unit management option

### Suppression strategy

The PLC program “Control Unit Switchover” operates according to the priorities of the control units and the active processes.

The priority depends on parameter `mmc_typ` in configuring file `NETNAMES.INI` (see paragraph above “Structure of the configuration file”).

If an MMC wants to go online to an NCU, it stores `mmc_typ` (priority) in its MMC_PLC interface. The Control Unit Switchover program evaluates this according to the following table:

<table>
<thead>
<tr>
<th>MMC property</th>
<th>Priority</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server</td>
<td>6</td>
</tr>
<tr>
<td>Main control panel</td>
<td>5</td>
</tr>
<tr>
<td>Secondary control panel</td>
<td>4</td>
</tr>
<tr>
<td>OEM-MMC 3</td>
<td>3</td>
</tr>
<tr>
<td>OEM-MMC 2</td>
<td>2</td>
</tr>
<tr>
<td>OEM-MMC 1</td>
<td>1</td>
</tr>
<tr>
<td>OEM-MMC 0</td>
<td>0</td>
</tr>
</tbody>
</table>

### Suppression rules

The following rules apply for the MMC suppression:

- High priority suppresses lower or equal priority subject to the following supplementary conditions:
  - Servers cannot be suppressed, as they require a permanent connection to each NCU.
  - MMCs on which the following processes are active cannot be suppressed:
    - Data transfer, e.g. from/to NCU
    - MMC is in the process of switching to the relevant NCU
    - MMC is just changing operating mode.
    - OEM disables switchover
- Equal priority of nodes between active MMC and competitor MMC:
  - The active MMC is suppressed

### 2.1.9 Connection and switchover conditions

In order to

- allow an MMC which is currently working offline to go online on a particular NCU or
- switch an MMC which is working online over to another NCU,

1. Call the channel menu on this MMC by pressing the channel switchover key
2. Select the channel group via a horizontal softkey
3. Select the appropriate vertical softkey for the channel. See 2.1.10.
2.1 Several operator panels and NCUs with control unit management option

The MMC is then switched to online operation or to another NCU, provided that its change in status is not blocked by one of the following conditions (displayed in message line).

Table 2-1 Messages associated with MMC switchover (MMC 103 without message number)

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Note
Corresponding messages are output without a message number on the MMC 103.

Additional messages can be generated in the MMC 100.2 and MMC 103 indicating the current status or errors in the configuration or the operating sequence.

For details see References: /DA/, Diagnostics Guide, Chapter 1

2.1.10 Implementation of control unit switchover

Control unit switchover is an extension of channel switchover.

Channel switchover

“Channel switchover” is a configuring means by which channels of any chosen NCUs can be grouped and named individually. MMC switchover to another NCU is implemented as part of channel switchover functionality.

Configuring of channels is based on file NETNAMES.INI. See 2.1.4.
2.1.11 User interface

**Function**

You can establish a connection between the MMC unit and one of the connected NCU/PLC units in every operating area.

Only the channels of the respective group are displayed. Activate the channel changeover key. The currently existing connection is displayed by means of the highlighted softkeys (horizontal, vertical) if the channel menu is active.

**Channel switchover**

You can change to other channels by means of the vertically arranged softkeys.

**Group switchover**

You can switch to another group by means of the softkeys on the horizontal menu (see previous Section); the channels of the currently selected group are now displayed on the vertical softkeys. Switchover to another channel (and if necessary to another NC) only takes place upon activation of a vertical softkey.

**NC switchover**

You can change to another NC via the vertical softkeys if the channel is not on the current NC.

Procedure: If required, configure a channel area NCs (horizontal softkeys 1–8) and put one channel from each NCU on vertical softkeys.

---

**Note**

The softkeys only offer the connections that are really assigned and whose channels are active in the respective NC.
2.1.12 Operator mode switchover

Two MMCs can be online at the same time on one NCU. In order to avoid both gaining write access to the same data or file simultaneously, there are two operating modes, i.e.

- the active and
- the passive operating mode.

Only one of the two MMCs can be active; the other is passive.

The interaction takes place according to the following rules:

**Active operating mode**

- The user requests active operating mode by pressing a key on the operator panel.
  - All operations and operating areas are activated.
  - Operator can operate and monitor.
  - The MCP assigned to the MMC is activated.
  - If data transfer processes (e.g. operation via V.24, reloading part programs, executing the job list, alarms) are running between the other MMC and the joint NCU, it cannot become active immediately.

**Passive operating mode**

- Passive mode is effective when the other MMC has requested active mode.
  - The connection to the NCU remains established.
  - All operations are deactivated.
  - Operator cannot operate. A window is displayed with header and alarm line and a message indicating “passive” state
  - The global menu is activated.
  - Any services initiated before (in active mode) remain active (e.g. operation via V.24, reloading part programs, executing the job list, alarms).
  - The MCP assigned to the MMC is deactivated.

The active operating mode can be selected by 2 different methods:

- Input key or
- Channel switchover key and channel selection
Rules for operating mode changeover

The following rules apply for changing the operating modes (see also Section 2.1.8 “Suppression strategy”):

- An MMC that goes online on an NCU is given active mode on it. If another MMC was already active on this NCU, it switches to passive mode if permitted by the PLC.

- If two MMCs are online, the operating mode is changed by pressing the key (“Input”, ENTER, RETURN) used to select the active operating mode.

- Changeover from the active to the passive operating mode might be rejected by the MMC if the current MMC application cannot be aborted or is still in progress. Likewise, active mode cannot be selected on an MMC if the other MMC currently linked to the NCU cannot be switched to passive mode.

- If an online request is issued by an MMC
  - and up to now no MMC is online:
    The MMC issuing the request goes online and switches to active mode. Any assigned MCP is activated by the PLC.
  - and an MMC is already online:
    This MMC switches to passive mode. The MMC issuing the request goes online and is given active mode.
  - and two MMCs are already online (both of secondary control panel type):
    The MMC active up to now switches to passive mode and is suppressed. The MMC issuing the request goes online and is given active mode.
  - and two MMCs are already online (one of main control panel type and in active mode, the other of secondary control panel type and in passive mode):
    The MMC active up to now switches to passive mode. The MMC that was passive up to now is suppressed. The MMC issuing the request goes online and is given active mode.
  - and two MMCs are already online (one of secondary control panel type and in active mode, the other of main control panel type and in passive mode):
    The MMC active up to now switches to passive mode and is suppressed. The MMC issuing the request goes online and is given active mode.

- If two MMCs are online on one NCU and the active MMC goes offline, it first switches to passive mode. Then the second MMC switches to active mode and the first one disconnects the link to the NCU.

Note
The MMC type is assessed as priority for the suppression strategy. See 2.1.8.

If the active MMC cannot be switched to passive mode, then the competing MMC is switched to passive mode.
2.1.13 MCP changeover

An MCP cannot be switched over independently of the MMC it is assigned to. It can be switched over only if

- the MMC switches over and
- the MCP address is stored in the MMC parameter block or the MMC–PLC interface (see paragraph "Structure of the configuration file" in this section).
- MCP_enable is set in the control unit switchover function on the PLC.

Activating/deactivating the MCP

If an MCP is assigned to the MMC in the NETNAMES.INI file, it is activated/deactivated as part of the operating mode change. The MCP switchover in the PLC is called by the operating mode change as a subfunction. The parameters for the MCP switchover are stored in the MMC-PLC interface.

<table>

2.1.14 PLC program “Control Unit Switchover”

Introduction

“Control unit switchover” is an important controlling function in the overall M:N strategy:

- MMC makes requests regarding the dynamic assignment of MMCs to NCU’s according to the configured options in NETNAMES.INI and displays information about existing links.
- The PLC control unit switchover checks the priorities of the requests and the states of the components involved and switches over if necessary.
- The NCU sets signals and evaluates signals required in connection with the control unit switchover function.

The control unit switchover function is a SW package in the toolbox. It is immediately available with its standard functionality, but can be modified for special applications according to individual requirements.

Provision is made for two categories of modification:

1. Simple parameterization of standard functionality
2. More fundamental re-configuring of the control unit switchover function

Reasons for more fundamental, user-specific re-configuring (2.) can be as follows:

- Suppression strategy which differs from standard functionality
- Operating mode switchover which differs from standard functionality
- Independent handling of override switch when switching over control unit
- Existence of a 2nd machine control panel on an MMC
Note
The logic in the MMCs (automatic control unit switchover) is fixed. It exists in two variants for the MMC 103.2 and 100.2. The flexibility of the solution in SW 5 includes the following features:

1. Configuring: NETNAMES.INI
2. See below for parameterization of standard functionality of PLC program “Control unit switchover”.
3. See Chapter 6 for more fundamental user-specific re-configuring.
Several OPs/NCUs (B3)

2.1 Several operator panels and NCUs with control unit management option

(1) Standard functionality

This is implemented as an optional PLC program.

Program structure

The control unit switchover program consists of:

1. FB101/DB101: Online/offline operating mode switchover
2. FB102/DB102: Active/passive operating mode switchover
3. FC103: Machine control panel switchover

Every program section is implemented in a separate function block (FB) or function (FC). The variables are stored in a separate instance data block (DB) for each FB. The control unit switchover main program is stored in FB101. The latter block must be called in an organization block (OB) to activate the functions. FB102 and FC103 are called repeatedly in MB101.

MCP switchover

The MCP switchover is not mandatory. It can be enabled or disabled via FB101/DB101 variable:

MSTT_enable

Assignment in the declaration table:

| TRUE   | MCP switchover is active |
| FALSE  | MCP switchover is not active, no FC103 call |

The MCP assigned to the active MMC is always activated. If the operating mode switchover function is disabled, then the MCP assigned to the last MMC to go online is activated.

Power-up condition:

To prevent the last selected MCP from being activated when the NCU is restarted, input parameter MCP1BusAdr should be set to 255 (address of 1st MCP) and MCP1Stop to TRUE (disable 1st MCP) when FB1 is called in OB100.

Enabling commands:

When one MCP is switched over to another, any active feed or axis enabling commands will remain operative.

Important

After an MCP switchover, the override switch on the new MCP is effective immediately.

The keys actuated at the instant of switchover remain operative. If no MCP is installed on the newly selected MMC, then it will not be possible to cancel the key functions from this MMC. Measures for situations of this type must be implemented in the PLC user program.

Operating mode switchover

The operating mode switchover is not mandatory. It can be enabled or disabled via FB101/DB101 variable:

aktiv_enable

Assignment in the declaration table:

| TRUE   | Operating mode switchover is active |
| FALSE  | Operating mode switchover is not active, no FB102 call |
2.1 Several operator panels and NCUs with control unit management option

**Error messages**
If disturbances occur (e.g. interface signal failure) while the program is running, corresponding alarms/error messages are transferred to data block DB2. 6 alarms are implemented:

1. Error in MMC bus address, MMC bus type
2. No confirmation MMC1 offline
3. MMC1 is not going offline
4. No confirmation MMC2 offline
5. MMC2 is not going offline
6. Online-request MMC is not going online (calling MMC)
and an error message:

Sign-of-life monitoring error

When the defaults in FB101 are left unchanged, the alarms begin at DB2.DBX188.0 (1st alarm) and end at DB2.DBX188.5. (6th alarm)

With variable `DBX.Byte_alarm`, the byte value for the 6 alarms can be changed from the default setting of 188. With variable `DBX.Byte_report`, the byte value of the operational message can be changed from the default setting of 192.

**Mixed mode**

Definition:
The term “mixed mode” refers to a state in which a conventional OP without control unit switchover function is connected to the first MMC interface on the NCU. The control unit switchover then operates exclusively on the 2nd MMC interface.

Parameter “MMC_mixed_mode” (variable in FB101/DB101) can be set to switch the operating mode from pure MMC operation to mixed mode.

To ensure that the control unit switchover function operates correctly in mixed mode, the following settings relating to mixed mode must be made:

FB101/DB101 variable:

`MMC_mixed_mode`

The following assignments must be made for an FB101 call:

**TRUE**
Mixed mode is active. Control unit switchover operates on the 2nd interface

**FALSE**
Mixed mode is not active. Control unit switchover operates on both interfaces

Supplementary conditions:

- A machine control panel (MCP) must not be configured for the first online interface. The first online interface is always assigned active mode status in mixed operation.
- To allow the second online interface to be assigned active mode status, it is possible to assign active mode status to both online interfaces in mixed operation. However, certain supplementary conditions apply.
2.1 Several operator panels and NCUs with control unit management option

**Warning**
When data are input from both control units simultaneously, there is a risk that inconsistent data will be transferred to the control.

**Server mode**
Once a server has occupied the online interface of an NCU, it cannot be displaced (suppressed) by any other device.

**Processing operating authorization for servers**
Three server-related program branches for handling MMC requests are implemented in the control unit switchover program:

1. Request for relinquishing operating focus
2. Request for setting operating focus
3. Relinquish operating focus

Each branch checks/processes the first and second online interfaces.

The requests are positively acknowledged if no switchover disabling commands are active. The “Relinquish operating focus” includes deactivation of the relevant machine control panel.

See also Figures 6-10 to 6-12.

**Wait times for acknowledgement signals**
To render the program independent of timers, two wait times based on repeated reading of the system time are implemented via SFC64 in the control unit switchover program. The wait times for acknowledgements can be changed if necessary by means of:

FB101/DB101 variables:
- `waiting_period_1` Wait for activation/online MMC
- `waiting_period_2` Wait for deactivation/offline MMC
- Wait for MMC sign of life

Values of between 0–32 (seconds) can be assigned to the FB101 variables. These values are entered in ms.

**Program integration**
If the control unit switchover program is to be called as a function in a higher-level PLC program, then it must be ensured that FB101, FB102 and FC103 and associated instance data blocks DB101, DB102 have not already been used elsewhere.

**Initialization**
When the NCU is restarted, all signals relating to control unit switchover on the PLC interface in DB19 are set to zero.
2.1 Several operator panels and NCUs with control unit management option

Note
Before an NCU is initialized, it must be ensured that it is not currently linked online to any MMC. It may be necessary to perform an MMC restart.

Resetting of interface by PLC
The interface signals relating to control unit switchover can be reset selectively as follows (without RESET on the NCU):

FB101/DB101 variable:
- initialization TRUE
  Reset signals in DB19 once. After signal reset the Initialization parameter is automatically reset to FALSE.

Sign-of-life monitoring
As soon as an MMC goes online, it sends a sign of life signal in DB10 DBB108, separately for both MMCs. If an MMC in online mode does not send a sign of life signal for longer than the time set in waiting_period_2, then the PLC program generates message: “Sign-of-life monitoring error”. This message is not cancelled until one of the MMCs is switched from offline to online mode again.

Identifier for MMC “Control unit switchover exists”
In certain operating states, MMCs must be able to detect whether the control unit switchover function exists. The “online request” interface signal in DB19.DBW110 m_to_n_alive is provided for this purpose. As soon as block FB101 is called in the PLC, it also sends a sign of life signal, consisting of the cyclic incrementation of m_to_n_alive (ring counter).

Generation after adaptations
After static parameters have been modified in FB101, DB101 must be
- deleted,
- generated again,
- called and stored.

2.2 Several operator panels and NCUs, standard functionality

The M:N system for all software versions without the Control Unit Management option is described below. The different performance levels of SW versions from 3.1 onwards are specified in connection with individual functions and as an overview in Chapter 3.

2.2.1 Configurations

Configuration parameters

As it is possible to freely combine hardware components, it is necessary to inform the system which components are combined and in what manner. On the MMC 102/103, this is done by means of an operator dialog in the Start-up area. In the case of the MMC 100/OP030, the configuration parameters are entered through the creation of a configuration file which is loaded for start-up. The file must be structured as described below.

| I | Identification of operator panel to which the configuration file applies. |
| II | Description of connection between operator panel 1 and NCU 1 |
|  | Description of connection between operator panel 2 and NCU 1 |
|  | or |
|  | Description of connections between operator panel 1 and NCU1, NCU2, NCU3 |
| III | Description of bus between the following components |
| IV | Description of component, operator panel 1 |
|  | Description of operator panel 2 component if configuration: 2 MMC, 1 NCU, (see Section 1) |
| V | Description of NCU component |
|  | Description of further components of NCU2, 3, 4, if configured as shown in Figs. 1-4 to 1-6. |

Fig. 2-4 Structure of configuration file NETNAMES.INI

Examples

For complete examples of configuration files, please refer to Chapter 6 of this Description.
2.2 Several operator panels and NCUs, standard functionality

Syntactic declarations

The configuration file must be generated as an ASCII file. The syntax is the same as that used in Windows *.ini files.

In the following tables, the components which the user may need to adapt or which he can name freely are typed in *italics*. Alternative passwords are specified separated by an |. Passwords must be typed in small letters.

Comments can be inserted in the parameter file. They must start with “;” and are limited on the right by the end of line. Blanks may be used as separators at any position except for in identifiers and passwords.

Number of configuration files

A configuration file is required for every connected operator panel. The configuration files of different operator panels included in one configuration differ from one another only in the first entry which contains the assignment of the file to a specific panel ([own] see below). For practical purposes, the core of the file is generated just once and then copied for the other panels. The identifier of the operator panel to which the file applies is then inserted in each copy.

I. Identification of operator panel

Identification of operator panel to which the configuration file applies.

Identifier

A description division of an operator panel must be generated with the selected identifier according to IV.

Keywords:

own Introduction identification division
owner Owner

II. Connections

Description of connections from the operator panel components to the NCU to be addressed. An entry of the following type is required for each operator panel.

Table 2-3 Description of connections OP – NCU

<table>
<thead>
<tr>
<th>Description division</th>

</tbody>
</table>

NCU_ID Entry for NCU component. One for SW 3.1

bel_name any name of max. 32 characters; with MMC 102/103

the name entered here (e.g. NCU1) is output in the alarm line

ncu_570 NCU type, (ncu_570 not applicable to configuration 1 MMC, 3 NCUs)

ncu_571 | ncu_572 | ncu_573

j Address of NCU component on the bus: \( j = 1, 2, \ldots, 15 \)

from SW 4.x: \( j = 1, 2, \ldots, 31 \)

*) The following applies when bus = mpi:

As the associated NCU is always assigned the next-higher address than the PLC, the PLC address must not be 31.

Address 31 can, for example, be assigned to an MMC.

Note

If the bus node addresses on the MPI bus are configured in conformance with SIMATIC, the configuring engineer can read out the assigned addresses using a SIMATIC programming device and use them to create the NETNAMES.INI file.

The following defaults are applied if no NETNAMES.INI configuring file has been copied into the MMC 100/OP030 or if the file cannot be interpreted:

- The bus type used is automatically determined
- MMC has address 1
- OP030 has address 10
- NCU and PLC both have address 13 for an OPI bus
- NCU has address 13 (from SW 3.5: 3) and the PLC has address 2 for MPI bus.
If the network configuration actually corresponds to these default settings, then it is not necessary to explicitly generate and load a NETNAMES.INI file. If, however, a special file is generated, then it must correspond exactly to the actual network on account of the special features described below.

**Compatibility**

The use of the above defaults establishes compatibility with earlier software versions for operation of the panel.

### 2.2.2 Switchover of connection to another NCU (SW 3.2 to 3.x)

**Operator interface**

The data area menu has been extended by the softkey “Connections”. This goes to a submenu in which the connections (conn_1, ..., conn_n) declared in NETNAMES.INI are displayed for selection via individual softkeys. The name (name=...) allocated in NETNAMES.INI to the connection is displayed on the softkeys. A connection to the new NCU is established by actuating the corresponding softkey.

In detail, the behavior depends on the type of MMC.

**Changeover behavior on OP030**

ONLINE change to another bus node is not possible on the OP030. The NETNAMES.INI file contains a permanently configured connection.

**Changeover behavior MMC100**

The softkey “Connections” is only displayed if more than one connection is implemented in NETNAMES.INI. When changing to the new NCU, the existing connection to another NCU is interrupted. When the changeover takes place, MMC applications must no longer have any need for a connection to the existing NCU (e.g. active data storing via V.24). If this rule is contravened, the control system outputs a corresponding message.

Concerning the NCU to which the changeover takes place, the MMC behaves as with a restart. It is positioned in the operating range preset as start operating range.

**Changeover behavior MMC 102/103**

The “Connections” softkey is only displayed if the M:N function is activated on the control. The “M:N” function is activated in the “Start-up/MMC/Operator panel” menu. All communications connections remain established with any changeover and the applications which have used these connections remain active. Concerning the new NCU, the MMC is after the changeover in the same operating range as before with another NCU.

**Possible defects**

With change of the connection to another NCU, it is possible that the NCU with which the connection is to be established rejects this. There may be a defect in the NCU or no other MMC unit can be operated at that time from the NCU any more.

MD 10134: MM_NUM_MMC_UNITS (number of possible simultaneous MMC communications partners) contains the setting which defines how many MMCs can be processed by an NCU at one time. OP030 requires one unit, MMC 100 or MMC 102/103 requires two units.
2.2 Several operator panels and NCUs, standard functionality

**Alarms/messages**

MMC 100, OP030
Only the alarms of the NCU with which a link is currently active can be output. Acceptance of configuration acc. configuration diagram in Chapter 1, subsection “Configurability”.

MMC 102/103
The alarms and messages of all connected NCUs can be processed simultaneously.

**Alarm text storage**

MMC 100, OP030
Only one version of the alarm texts can be stored on the operator component. The standard alarm texts are identical for all NCUs and exist in one version. The possible alarms of all connected NCUs must be stored in the single possible range for user alarms.

MMC 102/103
It is not possible to set up user alarm texts that apply specifically to the NCU (MMC only manages one alarm text file, SW 3.4 MMC 102/103).

**Link check**

MMC 100, MMC 102/103
The address of a connected NCU (on OPI bus only) can be altered in the “Connections/Service” menu. The new NCU address is stored on the NCU.

The softkey labeled “Service” is only displayed if the password for “Protection level service” has been entered.

When the function is started up, a direct connection between the MMC and the relevant NCU must be established before the address is altered to ensure that the address is not programmed more than once on the bus. (See paragraph “Power-up” below for instructions on modifying the address.)

---

**Note**

With replacement of the NCU (service case) or with failure of the backup battery, the address is no longer stored. A general reset on the NCU does not delete the NCU address. The address can only be changed via an MMC. To ensure that the current connection is shown in the basic display, the channel name must be assigned unambiguously in MD 20000: CHAN_NAME (channel name).

---

### 2.2.3 Switchover of connection to another NCU (SW 4 and higher)

---

**Note**

The channel menu function is an option and must be configured in the “NETNAMES.INI” file.
You can change to the channel menu in all operating areas by activating the channel switchover key. The only change is to the horizontal and vertical softkeys.

The horizontal softkeys are for selecting a channel group (max. 24), up to 8 connections to channels in different NCUs can be set up in one channel group.

The “Channel menu” screen displays all current communication connections and the associated symbol names.

### 2.2.4 Creating and using the configuration file

**MMC 100, OP030**

The NETNAMES.INI ASCII file generated on the PC/PG is loaded via the V.24 interface and permanently stored in the FLASH memory of the control units as described in:

**References:** /IK/, Installation Kit.

**MMC 102/103**

The NETNAMES.INI file can be processed directly with an editor (in menu “Start-up/MMC/Editor or DOS_SHELL”) on the hard disk of the operator component. The NETNAMES.INI file is stored in the installation directory:

```
C:\MMC2
```

from Software Version 4

```
C:\USER\NETNAMES.INI.
```

### 2.2.5 Power up

**Differences between MMC 100 and MMC 102/103**

Owing to the differences in operating and power-up characteristics, different start-up procedures are required for the two MMC types:

- MMC 100 always runs in “M:N” mode, when “M:N” is configured in the NETNAMES.INI file.

- The mode can be set in the “Start-up/MMC/Operator panel” menu on the MMC 102/103. The MMC 102/103 powers up as standard in a “1 : 1” link with an NCU, the NCU address can be specified directly in this case. If the “M:N” mode is set on the MMC 102/103, then the MMC searches the NETNAMES.INI file for the names of the partners specified for this function. The addresses are freely assignable.

  **Recommendation:**
  
  - Keep address 0 free (for PG )
  - Keep address 13 free (for service case: NCU replacement)

- The OP030 is not functionally capable of “M:N”. It can be used as a second operator panel that is permanently assigned to an NCU (“1 : 1” link). The addresses of the connected partners can be set for this purpose.
2.2 Several operator panels and NCUs, standard functionality

### Note
It is advisable to make a written record of the procedure (address assignments, etc.) beforehand.

#### Start-up
The NCUs are assigned bus address 13 in the delivery state. Every NCU on the bus must be allocated its own, unique bus address.

Addresses are assigned in:
- MMC: NETNAMES.INI file
- NCK: “Start-up/NC/NCK address” menu
- MCP: Switches... (address and baud rate if applicable, see also /Start-Up Guide/
  OB100 parameters: ...(see also FB1/P3/).

### Note
An NCK address is not deleted with “Delete SRAM” (switch S3= position “1” on NCU).

#### Power-up with MMC 100
The power-up process is the same as described in Section 2.1.6 for the MMC 100.2.

#### Power-up with MMC 102/103
The power-up process is the same as described in Section 2.1.6 for the MMC 102/103.

### 2.2.6 NCU replacement

In the case of NCU replacement or an additional NCU, the procedure is analogous to start-up (see 2.2.5).

#### Variant 1
1. Establish 1:1 connection between MMC and NCU
2. Power-up MMC on NCU with bus address “13” (see above)
3. Enter new NC address via the Start-up/NC/NC address operating area and boot NCU.
4. Wire bus again for M:N operation

#### Variant 2
1. The NCU, which is the “power-up NCU” for an MMC connected to the bus, is disabled. (The MMC powers up at the first connection configured in the NETNAMES.INI file)
2. Power-up MMC on NCU with bus address 13 (see above)
3. Enter new NC address via the Start-up/NC/NC address operating area and boot NCU.
4. Activating “Power-up NCU” again
2.2 Several operator panels and NCUs, standard functionality

Note

- Bus address 13 must be reserved for servicing purposes (i.e. must not be assigned to a bus node).
- MMC 100/100.2:
  The name length in file NETNAMES.INI (configuring in channel menu) is limited to 5 characters.
- MMC 102/103:
  The data "mst_address" is not evaluated, but used for the purpose of bus node documentation.
  If the channels are on different NCUs, "m:n" must be set in the operating area Start-up/MMC/Operator panel.

Data exchange between NC<->PLC

In configurations consisting of 1 x MMC and n x NCU, it is often necessary to synchronize the NCs.

The following synchronization options are available:

- NCK I/Os on drive bus (digital, analog, writing of NC and PLC).
- Normal PLC I/Os (I/O link).
- Link via PROFIBUS-DP (PLC-CPU315 required).
- Link via the global data function of SIMATIC S7 (PLC-CPU315 required).
  This option is also available on the PLC-CPU 314 with SW 3.5 and higher.
2.3 Restriction in relation to equipment

Rejection of link

On switchover to another NCU, the NCU selected for the new link may reject the connection. The cause may be a defect in the NCU or no additional MMC unit can be accepted. In this case, the MMC 100 automatically switches over to connection 1 after approx. five seconds. MMC 102/103 displays “#” for the variables.

Alarms, messages

Handling of alarms/messages is dependent on the MMC type:

1. MMC 100 / OP030
   Due to the equipment restrictions on driver level and the limited working memory, alarms/messages of only one NCU can be processed simultaneously.

2. MMC 102/103
   The MMC manages only one alarm text file. The NCU name assigned in the NETNAMES.INI file is displayed as the NCU identifier in front of every alarm or message. To obtain user texts specific to the NCU, it is possible to define user areas in the PLC for certain NCUs. The alarms/messages of all connected components can be processed and displayed simultaneously.

Operator interface

The operator interface characteristics depend on the MMC type.

1. MMC 100
   Fields and variables of one NCU can be displayed simultaneously in a window. Alarms and messages are displayed only by the NCU which is connected with the MMC.
   Up to four connections (one active connection (alarms, messages), three other connections) can be displayed simultaneously via user configuration (OEM), whereby all variables of a connection must be contained in one window (window-specific connections).

2. MMC 102/103
   Generally, fields and variables of different NCUs can be displayed in the same window (as OEM application).
   Alarms and messages can be displayed on all NCUs (to which the MMC has a connection).

3. OP030
   OP030 can only be configured as a “1 : 1” connection for an NCU.

When the MMC 100 and MMC 102/103 are used in the standard configuration (Chapter 1, subsection “Configurability”), it is not necessary to configure the operator interface. If variables of different NCUs must be output simultaneously in a display, configuration is necessary.

References:

References: /PK/, SINUMERIK MMC100/EBF Configuration kit

With MMC 100, all variables of a window must proceed from one NCU. With MMC 102/103, a suitable mixing of the variables of different NCUs is permissible.
2.4 NCU link

2.4.1 Introduction

Owing to the limitation on the memory and computing capacity elements, the number of channels or axes per NCU is restricted. A single NCU is not sufficient to fulfill the requirements made by complex and distributed machines, such as multi-spindle and rotary indexing machines. For this reason, the control system and closed-loop axis controls are distributed among several NCUs.

In order to ensure, however, that channels and axes can continue to operate on an interrelated, cross-NCU basis, the system provides so-called

- NCU Link functionality.

This includes:

Functional expansions

The following applications are possible in SW 5 and higher:

- Cross-NCU interpolation (coupling of setpoints, actual values and VDI signals)
- Real exchange of axes
- Cross-NCU access to axis values and axial system variables
- NCU-user communication supported by NCU link variables
- Generation of alarms on the NCU affected by an irregularity, even if the cause of the problem is on another NCU.
2.4.2 Technological description

Fig. 2-5 Sectional diagram of a drum changeover
Fig. 2-5 shows the main components of a simple multi-spindle plant. Several spindles are mounted mechanically on the drum, each of which can be used to perform a different machining operation. Together with the slide (X and Z axes), they form a machining station which is assigned to one channel. A workpiece is rotated by one spindle.

The workpiece to be machined is loaded and unloaded only once. The tool is mounted on the slide (e.g. X, Z axes). Various different tools can be loaded for each machining operation.

The tool is continuously assigned to the machining station. The workpiece-holding spindles are moved from one machining station to the next.

The spindle can only be checked for the current machining process. The channel must be able to address the slide axes and the current spindle at any given time. Every time a spindle moves on to the next machining unit, however, the spindle addressed by the channel must be a different machine axis. The "Axis container" concept solves the variable imaging of channel axes on machine axes. The machine axes might belong to another NCU connected by means of the NCU link. An accessible machine axis belonging to another NCU is referred to as a link axis (see 2.5).

The following subjects are closely related to the NCU link function and dealt with in separate subsections.

- Link axes
- Axis container
- User communication across the NCUs
- Configuration of the link grouping
2.5 Link axes

Note
NCU link is available in conjunction with MMC 103. The corresponding option is required to be able to define the number of available link axes.

Introduction
This subsection describes how an axis (for example, B1 in Fig. 2-6), which is physically connected to the drive control system of NCU2, can be addressed not only by NCU2, but also by NCU1.

Requirements
- The NCUs involved, NCU1 and NCU2, must be connected with fast link communication via the link module.

References: /PHD/, Configuring Guide NCU 571–573.2, link module
- The axis must be configured appropriately through machine data.
- The option link axis must be installed.
- The link communication must be activated with MD 18780: $MN.MM.NCU_LINK_MASK. The link grouping must be configured as described in 2.5.1.

Fig. 2-6 Overview of link axes
The following terms are important for understanding the subsequent description:

- **Link axis**
  Link axes are axes that are physically connected to another NCU and controlled by their servo loop. Link axes can be dynamically assigned to channels of another NCU. From the standpoint of a particular NCU, they are not local axes. The **axis container** concept described in 2.6 is for the dynamic change of assignment to a channel (special case: channel on another NCU). Axis exchange with GET and RELEASE from the part program is only available for link axes within an NCU. In order to cross the NCU link, the axis must first be placed in the NCU or a channel using the axis container function so that it can then be exchanged optionally in the same way as any other axis.

- **Local axis**
  A local axis is only addressed by the NCU to whose drive bus it is connected.

- **Link communication**
  The link communication is implemented on the NCUs involved by means of the link module. The link communication consists of setpoints, actual values, alarm handling, global variables (data) and signals (axis signals, PLC signals).

- **Home NCU**
  The NCU which establishes the drive bus connection for a link axis and implements the position control is called the home NCU of the link axis. In Fig. 2-6 NCU 2 is the home NCU for link axis B1.

- **Interpolation**
  The **link axis** option makes interpolation between local axes and axes on other NCUs possible for NCUs with link communication. If the interpolation is not only local, cyclical data exchange (setpoints, actual values, ...) takes place within an interpolation cycle. In particular, this causes dead time when waiting for external events.

- **Axis change**
  Use of a link axis by a specific NCU can change dynamically. An **axis container** mechanism is provided for this purpose as described in 2.6. The part program command GET is not available for link axes; the part program command GETD is only available within an NCU. Up to SW 4, it was only possible to exchange axes between different channels of an NCU.

- **Configuration of link axes**
  NCUs that want to use the link axes must configure the **NCU identifiers** for the home NCU of the link axis in addition to the usual channel and axis machine data.

- **Home channel**
  Channel in which the setpoint-generating part program for the axis is executed after the installation has powered up.
2.5 Link axes

Note
Link axes expand the limit set by the number of possible connections on the drive bus. With a maximum of 16 NCUs on the NCU link there are theoretical limits of max. 160 channels and 4960 axes/spindles. The following maximum values apply for one NCU: 31 simultaneous axes from 31 local and 32 link axes.

2.5.1 Configuration of link axes

SW 4
Up to SW 4, channel axes are directly mapped on the machine axes of the same NCU via MD 20070: AXCONF_MACHAX_USED (see Fig. 2-7 left).

SW 5
From SW 5, the channels operate with one of 31 logical axes from the logical machine axis image. This image points to
- local axes
- link axes
- container slots.

Container slots in turn point to
- local axes or
- link axes.

The following diagram illustrates the interrelationships:
With link axes

To enable link axes to be addressed throughout the system, the configuration must contain information about the axis NCUs. There are two types of NCU axis, i.e. local axes and link axes.

Differentiation local/link axes

The table that must be created via MD 10002: AXCONF_LOGIC_MACHAX_TAB is used to differentiate between local and link axes. See Fig. 2-7 center right and Fig. 2-8.

Note

The axis container functions are described in subsection 2.6.
Explanation

The logical machine axis image A addresses local machine axes B and link axes C.

The number of local machine axes in B is limited. The maximum permissible number for a specific system can be found in Catalog NC60.1.

All axes that can address the NCU are contained in B and C together.

Entries in A have the following format:

$\text{SMN}_A \text{CONF_LOGIC_MACHAX_TAB}[n] = \text{NC}_j.AX_i$

with

- $n$ index in Table A
- NC stands for NCU with
- $j$ NCU number, $1 \leq j \leq 16$
- $i$ axis number, $1 \leq i \leq 31$

Channel axes are no longer directly assigned to machine axes in MD 20070: AXCONF_MACHAX_USED as they were in SW version 4 and earlier, but are now assigned to logical machine axis image A.

Viewed from the part program, the only accessible machine axes are those which can be addressed by the channel (possibly via axis container, see below) via the logical machine axis image at a given point in time.
Default settings

By default, the settings of logical machine axis image A are local axis name AX1 for entry 1, and local axis name AX2 for entry 2, ... . With these, MD blocks that were generated for Software Versions lower than 4 can still be used with Software Version 5, if only local axes are addressed.

Examples

For example, the logical machine image can contain the following expressions:

- NC2_AX7: machine axis 7 of NCU 2
- AX2: local machine axis 2

If only expressions of the latter format AXi are entered in the logical machine axis image, this corresponds to a configuration up to Software Version 4, where only local axes are addressed.

Caution: The default settings are as follows:

- MD 10002: AXCONF_LOGIC_MACHAX_TAB[0] = AX1
- MD 10002: AXCONF_LOGIC_MACHAX_TAB[1] = AX2

Note

Another valid format for entries in the logical machine axis image A is:

- MD 10002: AXCONF_LOGIC_MACHAX_TAB[n] = CTx_SLy with
  - CT stands for container
  - x: container number, 1 <= x <= 16
  - SL stands for slot
  - y: Slot number, 1 <= y <= 32

Axis containers represent a grouping of axes which can be altered dynamically. Axis containers are described in Section 2.6.

2.5.2 Axis data and signals

Introduction

Axis data and signals for a link axis are produced on its home NCU. The NCU that has caused the movement of a link axis, is provided with axis data and signals from the system:
Implicitly active link communication

During interpolation, data are made available for axes which are physically subordinate to a non-local servo ( identifiable from entries in MD10002: AXCONF_LOGIC_MACHAX_TAB or axis container) via the link communication in the same manner as they are provided for local axes from the logical viewpoint of part programs. The procedure remains concealed from the applications.

Servo loop

The servo loop is implemented on the NCU on which the axis is physically connected to the drive. This NCU also contains the associated axis interface. The position setpoints for link axes are generated on the active NCU and transferred via the NCU link.

Communication types

There are two types of link communication:

- Cyclical communication
- Non-cyclical communication
2.5 Link axes

Cyclical communication
- Setpoint for the link axis,
- Actual values from the link axis
- Status signals of the link axis
- Status signals of the NCUs

are transmitted cyclically. Actual values and status signals of a link axis are updated and made available to the NCU that is interpolating this axis.

Non-cyclical communication
- Exchange of link variables
- Warm start requirements
- Activation of axis container rotation
- Modifications to NCU-global machine and setting data.
- Activation of axial machine data for link axes
- Alarms

Transfer time
Delays incur for transferring **setpoints** to the home NCU of a link axis and returning its **actual values**. With an interpolation group of local axes and link axes, the control delays the setpoints for the local axes of the interpolating NCU by one interpolation cycle, such that consistent values are taken into account for the interpolation.

If a channel needs the actual values of an axis of another NCU, e.g. a spindle with thread cutting, two interpolation cycles will lapse before they are available. The setpoints then generated are sent one interpolation cycle later to the position control for the above reason.

Response of the AXIS-VAR server to errors
If the server cannot supply any values for an axis (e.g. because the axis concerned is a link axis), then it returns a default value (generally 0).

For the purpose of testing, machine data 11398: AXIS_VAR_SERVERSENSITIVE can be used to set the axis data server sensitively so that it returns an error message rather than default values.

0: Default value
1: Error message

2.5.3 Supplementary Conditions

Output of alarms from position controller or drive
Axis alarms are always output on the NCU which is producing the interpolation value. If an alarm is generated for a link axis by the position controller, then the alarm is transferred to the NCU which is currently processing the interpolation.

On the assumption that axis alarms which cause the NCK-Ready relay to drop out (Nck-NoReady) are attributable to faults on the drive bus, the alarm is also output on the NCU to which the axis or the drive bus is physically connected. The reaction “Ready relay dropout” is only activated on this NCU.

Output of alarms following EMERGENCY STOP
If an EMERGENCY STOP request is activated by the PLC on an NCU, then all axes physically connected to drives on this NCU are switched to follow-up mode. This means that: even axes which are being interpolated by a different NCU are also switched to follow-up. Since this status prevents any further constructive machining operations on the other NCUs, an additional alarm is generated which is designed to stop all axis motions instantaneously.
This additional alarm must be acknowledged by an operator panel reset. If the original (EMERGENCY STOP) alarm is still active at this time, then the additional alarm can be successfully reset, but another alarm (self-clearing) is then produced which prevents axis motion or a new program start until the original alarm has been acknowledged.

**Output of alarms with alarm reaction NCK-NoReady**

If a serious alarm resulting in dropout of the NCK-Ready relay is activated on an NCU, then the effects of the alarm will apply to all other NCUs which are addressing an axis via link communication on the first NCU. An additional alarm which causes all other axes to stop instantaneously is activated on each of the other NCUs.

For alarm acknowledgement, see EMERGENCY STOP.

**Compensations**

The compensation functions

- CEC
- EEC
- QEC

are not available for link axes.

**Switching off grouped NCUs**

If an NCU assigned to an NCU grouping is switched off or restarted by NCK RESET, then the other NCUs in the grouping are also affected (see also 2.8). An alarm is generated on the NCUs which are still running to prevent them continuing with the machining operation.

**Powering up an NCU grouping**

If one NCU in the grouping is restarted, e.g. due to changes to machine data, then the other NCUs in the grouping also execute a warm restart.

**Nibbling and punching**

To execute nibbling and punching operations, high-speed inputs and outputs must be connected and parameterized on the “interpolation” NCU (on which the part program is being executed). Commands “High-speed nibbling and punching”, e.g. PONS and SONS are not available for link axes.

**Travel to fixed stop**

If an axis container axis is being held against a fixed stop, the axis container cannot rotate. Axes can travel to fixed stops on different NCUs and be subsequently clamped without restriction.

**Frames**

Link axes can only be included in the program commands for frames if they are also designated as geometry axes. The command changes the geometry only for the channel to which the axis is currently assigned. A frame command for an axis which is not defined as a geometry axis is rejected with alarm 14092.

**Revolutional feedrate**

Although setting data 43300: ASSIGN_FEED_PER_REV_SOURCE referred directly to a machine axis in SW 4 and earlier, the MD refers in SW 5 and higher to the logical machine image and, via this, to a machine axis (local or link axis).
2.5.4 Programming with channel and machine axis identifiers

Channel axis identifiers

Example:
WHenever $AA_IW[Z] < 10 DO ... ;Current position of the Z axis

Machine axis identifiers

Example:
WHenever $AA_IW[AX3] < 10 DO ... ;Scan current position of machine axis AX3

This method of programming is permitted only if machine axis AX3 is known in the channel at the time of scanning.

Note
In SW 5.2 and higher, system variables which can be used in conjunction with channel axis identifiers are specially marked in the “Advanced” Programming Guide (Appendix).

2.5.5 Flexible configuration

Introduction
Rotary indexing machines and multi-spindle machines have special requirements as regards the flexible assignment of channel axes to machine axes.

Requirement profile
When advancing the table of the rotary indexing machine or the drum of the multi-spindle machines the axes/spindles are brought to a new station or position. The NCU which controls the axes of a station as local axes must be able to address the newly changed axes/spindles. The hitherto addressable axes/spindles can now be discarded for this purpose.

Solution
A configuration of the relevant axes in an axis container specified in machine data enables different machine axes to be located in succession behind a channel axis that remains constant. Advancing the rotary table or drum is performed synchronously with the advancing of the axes entered in the axis container.

Axes in an axis container can also be configured as geometry axes.

Note
The axis container has no mode group reference, i.e. the workpiece-holding, travelling axis can change from one mode group to another at different machining stations.
2.6 Axis container

Definition

An axis container can be imagined as a circular buffer in which

- local axes and/or
- link axes

are assigned to channels. Axes in an axis container are also referred to as **container axes**. Assignments can be “shifted” (“rotation” of the circular buffer) by means of program commands. The term “axis” in this case refers to both axes and spindles. All machine axes in the axis container must be assigned to exactly one channel axis at any given point in time.

---

Note

Rotation of the drum or rotary table is analogous to the rotation of the circular buffer with the assigned axis entries.

---

Description

The link axis configuration described in Section 2.5.1 allows reference to be made to axis containers in the logical machine axis image, in addition to direct reference to local axes or link axes. This type of reference consists of:

- container number and
- slot (circular buffer slot within the corresponding container)

An entry in a circular buffer is either:

- a local axis or
- a link axis

(either axis or spindle)

Axis container names in SW 5.2 and higher

Axis container names can be freely defined with machine data MD 12750 : AXCT_NAME_TAB in SW 5.2 and higher. The names assigned can then be used:

- in axis container rotation commands AXCTSWE( ) and AXCTSWED( ) to address the container to be rotated and
- when scanning the states of axis containers using system variables:
  - $AC_AXCTSWA[ ]
  - $AN_AXCTSWA[ ]
  - $AN_AXCTAS[ ]

SW 5.1 Parameter CTI

In this software version, **channel axis identifiers**, which refer to the container to be rotated via the logical machine axis image, must be used instead of axis container identifiers.

Definition of container contents

Machine data MD 12701 ... 12716:

$MN_AXCT_AXCONF_ASSIGN_TAB1 ...n defines the default assignment between an axis container slot and a machine axis within an NCU grouping for axis container 1...n. The assignment between an axis container slot and the selected channel is programmed in MD 20070:

$MC_AXCONF_MACHAX_USED and MD 10002:

$MN_AXCONF_LOGIC_MACHAX_TAB.
In the example illustrated in Fig. 2-11, the 3rd channel axis (3rd entry in $MC_AXCONF_MACHAX_USED) is a container axis. The 3rd entry in $MC_AXCONF_MACHAX_USED refers to the 8th entry in $MN_AXCONF_LOGIC_MACHAX_TAB and this (CT3_SL2) in turn to the 3rd axis container and its container slot 2. This 2nd entry in $MN_AXCT_AXCONF_ASSIGN_TAB3 (NC3_AX1) defines the 1st machine axis of NCU3 as a container axis of axis container 3, i.e. in the initial state, the 4th channel axis is the 1st machine axis of NCU3.

The 5th channel axis is also a container axis: The 5th entry in $MC_AXCONF_MACHAX_USED refers to the 7th entry in $MN_AXCONF_LOGIC_MACHAX_TAB and this (CT1_SL1) in turn to the 1st axis container and its container slot 1. This 1st entry in $MN_AXCT_AXCONF_ASSIGN_TAB1 (NC1_AX1) assigns the 1st machine axis of NCU1 to the 1st slot of axis container 1, i.e. in the initial state, the 1st machine axis of NCU1 is assigned to the 5th channel axis.

Fig. 2-11  Mapping of channel axes via the logical machine axis image onto axis container
Axis container entries contain local machine axes or link axes from the view of an individual NCU. The entries in the logical machine axis image MD10002: AXCONF_LOGIC_MACHAX_TAB for a single NCU are permanent.

The contents of the axis container slots are variable inasmuch as the contents of the circular buffer (axis container) can be shifted together by \( \pm n \) increments. The number of increments \( n \) is defined for each axis container in SD 41700: $SN_AXCT_SWWIDTH.

The number of increments \( n \) is evaluated modulo in relation to the number of actually occupied container slots. In doing so, new contents are created for all slots of an axis container (exception: 0 and slot number = increment number).

System variables provide information about the current status of an axis container; these system variables can be read addressed from the part program and synchronized actions. See 2.6.1.

### Container rotation

### Frames and axis container rotations

The assignment between channel axes and machine axes can change when the axis container rotates. The current frames remain unchanged after a rotation. The user himself is responsible for ensuring that the correct frames are selected after a rotation by, for example, programming basic frame masks.

### Activation of axis container rotation

The application must ensure that the desired local or link axes are addressed by issuing commands in the part program for rotating the axis container to a specific position.

---

**Fig. 2-12** Shifting the entries to the axis container slots

The axis container model has the following characteristics:

- A channel always sees a fixed number of axes with defined channel axis names (logical machine axis image)
- The “rotation” of the axis container sets new machine axes for all channels that have axes in the same axis container.
For example, when rotating the drum of a multi-spindle machine into a new position, it must be ensured that each position addresses the newly changed spindle by rotation of the axis container.

**Note**

Axis containers can be used jointly by different channels of an NCU and by channels of other NCUs.

If axes of different channels display reference to the same axis container via the logical machine axis image, then all channels concerned see different axes after a rotation. Consequently: The time for a rotation must be coordinated between the channels. This is performed by means of the available language commands.

Each entry in the axis container must be assigned to the correct channel at all times. The system variables in 2.6.1 offer the possibility for the part program or synchronized action to gain information about the current axis container state.

### Commands for the axis container rotation

The requirement outlined above for coordinating channels that jointly use an axis container is contained in the effects of the command **AXCTSWE**.

**Notation:**

**AXCTSWE**(CT1, CT2, ... CTi) ;The function name stands for:  
:AXis ConTainer SWitch Enable

CT1, CT2, ... CTi are the identifiers of the axis containers that must be advanced. The increment must be stored in setting data SD 41700: AXCT_SWWIDTH[container number]

SD 41700: AXCT_SWWIDTH[container number]

(container-specific). The SD 41700: AXCT_SWWIDTH (AXis ConTainer SWitch Width) is available to all NCUs via the link module (i.e. all NCUs connected via a link module "see" the same values).

**Function:**

Each channel whose axes are entered in the specified container issues an **enable for a container rotation** if it has finished machining the position/station. If the enables for all channels for the axes of the container have been received, container rotation takes place with the increments set in SD 41700: AXCT_SWWIDTH[container number] (the direction of rotation is also assessed if there is a leading sign).

The following variant is provided to simplify start-up:

**AXCTSWED** (CT1) ;The function name stands for:  
:AXis ConTainer SWitch Enable Direct

The axis container rotates according to the settings in setting data SD 41700: AXCT_SWWIDTH[container number]. The call may be used only if the other channels containing axes in the container are in the **RESET** state.
2.6 Axis container

### Note
In SW 5.2 and higher, the axis container names assigned in MD 12750: $MN_AXCT_NAME_TAB can be used for commands AXCTSWE and AXCTSWED.

In the earlier software version SW 5.1, channel axis identifiers must be specified which refer to the container to be rotated via the logical machine axis image. The rotation must be specified in a separate command AXCTSWE(channel axis) for each container.

### Implicit wait
There is an implicit wait for the completion of a requested axis container rotation if one of the following events has occurred:

- Part program language commands which will cause a container axis assigned to this axis container in this channel to move
- GET(channel axis name) for an appropriate container axis
- The next AXCTSWE(CTi) for this axis container

### Note
Even an IC(0) will result in a wait including synchronization where necessary (block-by-block change in addressing according to increment even though absolute dimension is set globally).

### Synchronization with axis position
If the new container axis assigned to the channel after a container rotation does not have the same absolute machine position as the previous axis, then the container is synchronized with the new position (internal REORG).

### Note
The SD 41700: AXCT_SWWIDTH[container number] is only updated for new configurations. If after the incremental rotations of the RVM/MS the position has reached a switching position before the original position, the container can continue to be rotated forwards, in order to reach the original position of the container again. The drum or rotary table must however be turned back to the original position, so that measuring and supply cables are not interrupted.
Home channel of a container axis

If more than one channel has access authorization (i.e. a “reference”) to the axis due to the setting in MD 20070: AXCONF_MACHAX_USED, the write access to the axis (setpoint input) can be passed on. Machine data MD 30550: AXCONF_ASSIGN_MASTER_CHAN creates a default assignment between an axis and a channel. MD 10002: AXCONF_LOGIC_MACHAX_TAB is set to define which NCU “possesses” the axis after power-up or is producing the interpolation value. Since the axial machine data for link axes are identical on all NCUs, MD 30550: AXCONF.Assign_MASTER_CHAN is evaluated only if the NCU has write authorization to the axis (see logical machine axis view in MD 10002: AXCONF_LOGIC_MACHAX_TAB).

Axis replacement

Passing the write authorization to an axis (setpoint input) by means of Get, Release,..., works for a container axis in the same way as for a normal axis. Write authorization can only be replaced between the channels of one NCU. Write authorization cannot be passed beyond the boundaries of an NCU.

2.6.1 System variables for axis containers

The following system variables allow part programs and synchronized actions to access information about the current state of an axis container.

Legend:

- **r**: Read
- **PP**: Part program
- **SA**: Synchronized action
- **SW**: Software version
- **n**: Axis container identifier with SW 5.2 and channel axis identifier with SW 5.1

#### Activity of drum/rotary table/axis container

Fig. 2-13 Axis container rotation dependent on enable by channels concerned
2.6.2 Machining with axis container (schematic)

![Diagram of machining with axis container](image)

**Note:**
An NCU machining cycle which is in charge of the rotation of the rotary table or the drum for multi-spindle machines contains the query of enables for container rotation of all NCUs concerned. If all enables are present, switching to the next position/station takes place. The axis containers are rotated accordingly.
2.6.3 Axis container behavior after power ON

The container always assumes the state defined in the machine data when the power is switched on, irrespective of its status as the power supply was switched off, i.e. the user must distinguish between the actual status of the machine and the default setting and compensate accordingly by specifying appropriate axis container rotations. He can do this, for example, by means of an ASUB containing AXCTSWED in one channel while the other channels are still in the RESET state.

2.6.4 Axis container response to mode switchover

A container axis in an axis container which has been enabled for rotation cannot be traversed in JOG mode. An axis container can only be rotated in JOG mode by means of an ASUB.

2.6.5 Axis container behavior in relation to ASUBs

An enabling command for axis container rotation cannot be cancelled, i.e. if an axis container rotation has been enabled in an ASUB, the enabling command remains effective even when the ASUB has ended.

2.6.6 Axis container response to RESET

A reset cancels the enabling command for axis container rotation. The reset channel is then no longer involved in the axis container rotation. The enabling commands in the other active channels can effect a rotation. If all channels except one have been reset, the one remaining active channel can set the rotary position directly with AXCTSWED.

2.6.7 Axis container response to block searches

An axis container rotation (AXCTSWE) cannot be enabled and activated in one block, but the enabling and activation commands must be programmed in separate action blocks. In other words, the axis container status changes in response to each separate rotation command as a function of the status of other channels.

2.6.8 Supplementary conditions for axis container rotations

Note

Through appropriate programming measures, the user must ensure that
– the right zero offsets are effective after the container switch and
– that no transformations are active during the container switch.
Axial machine data

If an axis is assigned to an axis container, then certain axial machine data must be identical for all axes in the axis container as the data are activated. This can be ensured by making a change to this type of machine data effective all container axes and all NCUs which “see” the axis concerned. The message: “Caution: This MD will be set for all container axes” is output at the same time.

During power-up, all axial machine data of this type are synchronized with the values of the machine axis in slot 1 of the axis container. In other words, the relevant machine data are transferred from the machine axis in slot 1 of the axis container to all other container axes. If machine data with other values are overwritten by this process, the message: “The axial MD of the axes in axis container <n> have been adapted” is output.

If a slot in the axis container is re-assigned (through writing of machine data MD12701–12716: AXCT_AXCONF_ASSIGN_TAB<n>), then the following message is output: “The MD of the axes in axis container <n> will be adapted on next power-up”.

Axial machine data of the type discussed above are identified by attribute containerEqual (equal for all axes in the axis container). With an NCU link, the axis container is defined on the master NCU (see Section 2.4).

Axis states

If a container axis is active in axis mode or as a positioning spindle (POSA, SPOSA) and its axis container needs to be rotated, then the rotation cannot be executed until the container axis has reached its end position.

A container axis which is active as a spindle continues to turn as the axis container rotates.

SPCON (switchover to position control) is “attached” to the physical spindle, i.e. this status is passed on with the spindle when an axis container rotates. SETMS (master spindle), on the other hand, refers to the channel and remains active in the channel when an axis container rotates.

Continuous path mode G64

An axis container rotation interrupts G64 mode in a channel in which a container axis in the rotating container is also a channel axis, even if it does not belong to the path grouping. This interruption does not occur, however, until an axis in the rotated axis container is programmed again.

PLC axes

If a container axis in a container which is enabled for rotation must become a PLC axis, then this status change request is stored, and the changeover to PLC axis status does not take place until after completion of the axis container rotation.

Command axes

A container axis in a container enabled for rotation cannot be declared a command axis. The traverse request is stored in the channel and executed on completion of the axis container rotation.

Exceptions to this rule are synchronized actions M3, M4, M5 and a motion-changing S function: If an axis container rotation is active and the spindle is transferred to the control of another NCU, alarm 20142 (channel %1 command axis %2: Invalid axis type) is output. These synchronized actions do not change a channel axis into a command axis, but leave it in its original state. Synchronized actions of this type cannot be stored.
References: /FBSY/ Description of Functions Synchronized Actions

**Reciprocating axes**
A container axis in a container enabled for rotation cannot become a reciprocating axis, i.e. this change in status does not take place until the axis container has finished rotating. The status change command remains active.

**Axis couplings**
An axis container cannot rotate while an axis coupling, in which one of its container axes is involved, is still active. The coupling must be deselected (COUPOF) prior to rotation and selected again (COUPON) afterwards. A new COUPDEF command is not necessary.

**Compile cycles**
In SW 5.2, a compile cycle axis cannot be a container axis.

**Main run offset values**
The main run offset values (DRF offset, online tool offset, synchronized action offset, compile cycle offset) for a channel axis assigned to a container slot remain valid after the relevant axis container has rotated. External zero offsets cannot remain valid after an axis container rotation as these refer to specific machine axes. If an external zero offset is active, the axis container rotation is rejected with alarm 4022.

**Axial frame**
The axial frame of a channel axis, which is also a container axis, is no longer valid after an axis container rotation. Since the axis container rotation assigns a new machine axis to the channel axis, but the axial frame is referred to a machine axis, the rotation thus also changes the axial frame. If the two frames do not coincide, a synchronization process (internal REORG) is performed.

The assignment between a channel axis and a machine axis is altered by the axis container rotation. The current frames remain unchanged after a rotation. The user himself is responsible for ensuring that the correct frames are selected after a rotation by, for example, programming basic frame masks.

**Transformations**
If the container axis is a spindle which is involved in a transformation, then the transformation must be deselected before the axis container rotation is enabled. Otherwise alarm 17605 is activated.

**Gantry grouping**
Gantry axes cannot be axes in an axis container.

**Drive alarms**
When a drive alarm is active for a container axis, then the associated axis container cannot rotate until the alarm cause has been eliminated.
2.7 Cross-NCU user communication, link variables

Introduction
For large machine tools, rotary indexing machines and multi-spindle machines, whose movement sequences are controlled by more than one NCU, the applications on a single NCU must be able to exchange information rapidly with the other NCUs connected via link module.

For this purpose there are:
- Link variables

2.7.1 Link variables

Definition
Link variables are system-global data that can be addressed by the connected NCUs as system variables if link communication is configured. The contents of these variables, their data type, their use, their position (access index) in the link memory are defined by the user (in this case this is usually the machine manufacturer).

Precondition
- To active NCU link communication, MD 18780: MM_NCU_LINK_MASK must be set.
- The link grouping must be installed and configured according to 2.8.

Application
As link variables are formally system variables, they can be read/write accessed in
- part programs
- synchronized actions
(as a rule).

Access possibilities for the individual link variables are specified under 2.7.2.

Note
On installations without an NCU link, the link variables can also be used NCU-locally as an additional means of cross-channel communication.

Structure
Each NCU connected to an entire system with link module sees a link memory in which the link variables are stored uniformly. Data exchange takes place after changes in the following interpolation cycle.
2.7 Cross-NCU user communication, link variables

Size of link memory

The size of the link memory can be configured within the limits set by machine data

\[
\text{MD 18700: MM\_SIZEOF\_LINKVAR\_DATA.}
\]

It is necessary to define the same size for all connected NCUs. If there are deviations, the system adapts the link memory size of all NCUs according to the largest size specified. If the memory area of the link memory is exceeded during an access attempt, alarm 17020 is output.

Initialization of link memory

After power-up, the link memory is initialized with 0.

Data types of link variables

The link memory can contain link variables with the following data types:

- INT $A\_DLB[i]$ ; Data Byte (8 bits)
- INT $A\_DLW[i]$ ; Data Word (16 bits)
- INT $A\_DLD[i]$ ; Data Double word (32 bits)
- REAL $A\_DLR[i]$ ; Real data (64 bits)

According to the data type, 1, 2, 4, 8 bytes are addressed when reading/writing the link variables.

The position offset in bytes in the data area for global data is determined directly by the programmed field index. This is thus independent of the data type and specifies the offset in bytes.

Range of values

The data types have the following value ranges:

- BYTE: \(-256 \text{ to } 255\)
- WORD: \(-32768 \text{ to } 65535\)
- DWORD: \(-2147483648 \text{ to } 2147483647\)
- REAL: \(-4.19\times10^{-308} \text{ to } 4.19\times10^{-307}\)

Alarm 17080 is generated when the upper value range limit is violated and alarm 17090 with violation of the lower value range limit and alarm 14096 in the case of an illegal type conversion.

Addressing with access to global variables

Index i always represents the distance in bytes from the beginning of the link memory. The index is counted from 0. This means that:

<table>
<thead>
<tr>
<th>Type</th>
<th>Interpretation of (i)</th>
</tr>
</thead>
<tbody>
<tr>
<td>$A_DLB[i]$</td>
<td>After byte i there is a data of the byte type. $A_DLB[7]$ addresses the byte 8 from the beginning of the link memory.</td>
</tr>
<tr>
<td>$A_DLW[i]$</td>
<td>After byte i there is a data of the word type. $A_DLW[4]$ addresses the word which is located on byte 5 from the beginning of the link memory.</td>
</tr>
</tbody>
</table>
### 2.7 Cross-NCU user communication, link variables

<table>
<thead>
<tr>
<th>Type</th>
<th>Interpretation of (i)</th>
</tr>
</thead>
<tbody>
<tr>
<td>$A_{DLD}[i]$</td>
<td>After byte i there is a data of the double word type. $A_{DLD}[12]$ addresses the double word which is located on byte 13 from the beginning of the link memory.</td>
</tr>
<tr>
<td>$A_{DLR}[i]$</td>
<td>After byte i there is a data of the real type. $A_{DLR}[24]$ addresses the real value which is located on byte 25 from the beginning of the link memory.</td>
</tr>
</tbody>
</table>

#### Link memory use

The link memory can have different assignments for processes that are completely separated in time. The various NCU applications that access the link memory jointly at any one time must use the link memory in a uniform way.

**Access from synchronized actions**

If an impermissible index is used for access to the link memory from a synchronized action or a part program, alarm 20149 is issued.

**Write access to link variables**

When writing to link variables of the link memory, for example as follows

$$A_{DLB}[5] = 21,$$

a write element is required. The write element serves for communication with further NCUs which must see the modified contents in the link memory. Each write process to a link variable requires a write element. It is busy with the write process until the main run executing data exchange with the other NCUs is completed.

Since global data can be written by all channels and NCUs, the user must ensure proper coordination of write and read access operations. Variables are written immediately if an NCU link connection is active. Writing and immediate readback of a variable produces the same result. Variables are written only in synchronism with the main run. Writing and immediate readback in the same part program block produces a different result.

**Number of write elements**

The write elements available for writing to link variables are limited. Their number is defined in:

MD 28160: MM_NUM_LINKVAR_ELEMENTS.

If no more write elements are available for an intended write process, alarm 14763 is issued. The set number of write elements only limits the number of write processes that can be written in one block.

**Dynamic response during write**

Writing the link variables is immediately completed for the local NCU in the current interpolation cycle (in the sequence of commands). If the user does not exceed the number of possible write processes (can be checked in system variable $A_{LINK_TRANS_RATE}$) in the current interpolation cycle, all other NCUs will have access to the written information 2 interpolation cycles later. If link variables are used exclusively to coordinate the channels of a multi-channel NCU, they can be written in the same interpolation cycle.
Note

The user (machine manufacturer) must ensure that the time is consistent for larger data blocks that are logically associated with one another. Transfer takes place word by word. The data quantity which can be transferred in the same interpolation cycle is specified in system variable $A\_LINK\_TRANS\_RATE$ (see below). A transmission can be protected by marking variables of the link memory as semaphores.
### 2.7.2 System variables of the link memory

The following system variables are available for accessing the link memory:

**Legend:**
- **r** Read
- **w** Write
- **R** Read with implicit preprocessing stop
- **W** Write with implicit preprocessing stop
- **PP** Part program
- **SA** Synchronized action

<td>r</td>
<td></td>
</tr>
</tbody>
</table>

**Note**

Use of index i is described in detail in 2.7.1.
2.8 Configuration of a link grouping

Introduction

The preceding chapters described how to configure link axes and axis containers. Both require a link communication to be established between the NCUs concerned. Setting up the link communication takes place by means of:

- The link module hardware
  
  References: /PHD/, Configuring Guide NCU 571–573.2

- Machine data

The following section describes how to use the required machine data.

![Diagram of link grouping](image)

Fig. 2-15 Link grouping

Link grouping

A link grouping consists of a minimum of 2 and maximum of 16 NCUs interconnected by link modules.

- The link module master (MD 12510: NCU_LINKNO = 1) plays a leading role in this process. It synchronizes the interpolation cycle and sets up slave communication in power-up. It is advisable to assign the NCU numbers in continuous ascending order for the slave modules.

- The first and last module in the physical chain must activate the bus terminating resistances.

- The software version must be identical on all NCUs in a link grouping.
Machine data

MD 18780: MM_NCU_LINK_MASK ensures that link communication is established. It provides the dynamic memory space that is required for communication in the NCUs equipped with link modules.

Machine data
MD 12540: LINK_BAUDRATE_SWITCH specifies the data transfer rate of the link communication with the following assignment:

<table>
<thead>
<tr>
<th>Set value</th>
<th>Rate</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>9,600 Kbaud</td>
</tr>
<tr>
<td>1</td>
<td>19,200 Kbaud</td>
</tr>
<tr>
<td>2</td>
<td>45,450 Kbaud</td>
</tr>
<tr>
<td>3</td>
<td>93,750 Kbaud</td>
</tr>
<tr>
<td>4</td>
<td>187,500 Kbaud</td>
</tr>
<tr>
<td>5</td>
<td>500,000 Kbaud</td>
</tr>
<tr>
<td>6</td>
<td>1,500 Mbaud</td>
</tr>
<tr>
<td>7</td>
<td>3,000 Mbaud</td>
</tr>
<tr>
<td>8</td>
<td>6,000 Mbaud</td>
</tr>
</tbody>
</table>
| 9         | 12,000 Mbaud| Default setting

Machine data  MD 12550: LINK_RETRY_CTR specifies the maximum number of times the link communication is repeated when an error occurred during frame transfer.

Machine data  MD 12530: LINK_NUM_OF_MODULS specifies the number of link modules taking part in the link communication.

Machine data  MD 12510: NCU_LINKNO assigns a logical link number to an NCU; this number is used for link identification in conjunction with link axes and link communication. Identifications can be assigned independently of the physical sequence of the modules in the link string. The module with NCU_LINKNO = 1 is master.

Warning
Assignment of NCU_LINKNO must be unambiguous. An alarm is issued if there is an error.

Machine data  MD 12520: LINK_TERMINATION specifies for the software which NCUs correspond to the bus terminating resistances. The numbers set refer to the entries defined in MD 12510: NCU_LINKNO. 0 corresponds to the first definition, 1 to the second, etc. from MD 12510: NCU_LINKNO.

Note
MD 12520: LINK_TERMINATION need only be set for the prototype hardware of the link module. It is only meaningful for the software.
2.8 Configuration of a link grouping

The NCUs that are physically connected at the beginning and end of the bus must activate the terminating resistors. This measure is necessary for the link communication to work.

Machine data

MD 30554: AXCONF_ASSIGN_MASTER_NCU
defines for the purposes of power-up which NCU in an NCU grouping will be responsible for generating the axis setpoint (master NCU).

Machine data

MD 30560: IS_LOCAL_LINK_AXIS
specifies that the axis drive needs to be started during power-up, even if the axis is operating under the control of another NCU. It is evaluated only if machine data required to create a link grouping have been set, but link communication has failed due to an error.

Note

It may be necessary to increase the interpolation cycle due to the number of link axes and write elements.
Supplementary Conditions

3.1 Several operator panels and NCUs with control unit management option

Configuration

The number of configurable control units is only limited by the availability of bus addresses on the individual bus segments of the different bus types.

The restrictions relating to the current SW version specified in the catalog or release notes apply.

Availability

The control unit management option is available in **SW 5.3** and later.
3.2 Several operator panels and NCUs, standard functionality

Availability from SW 3.1
Configuration of “several operator panels and several NCUs”: available in the basic version. The number of NCUs that can be connected is limited to 1 and the operator panels to 2. One of the panels must be an OP030. Programming language Step 7 can be used.

Expansions from SW 3.2
Configuration “1 operator panel and up to 3 NCUs” available according to Figs. 1-2 and 1-3.
When the link is created via the MPI line (187.5 kbps), a PLC-CPU315 must be used if the configuration includes more than one NCU since this PLC allows variable setting of the NC address. Addresses must likewise be specified for exchange of data between PLCs via PROFIBUS-DP (PLC-CPU315 only) or for global data (duplicate address assignments).

Expansions from SW 3.5
Configuration “1 operator panel and up to 4 NCUs and locally 1 MMC each” available according to Fig. 1-4. Data exchange between NC and PLC is now also available with the PLC-CPU 314.

Expansions from SW 4
Operation of the m:n connection via the channel menu (see section 2.1.11), which can be selected via the “Switchover channel” key. Prerequisite for the channel menu is a configuration via the NETNAMES.INI file (see /IAD/, Installation and Start-up Guide 840D, section MMC). The channel menu function is an option.
Bus connection:
The address space (previously 0, ..., 15) has been extended to (0, ..., 31).

Note
If an address higher than 15 is used, all components connected to the bus must be capable of processing addresses between 0 and 31.
3.3 Link axes

Availability

1. Precondition is that the NCUs are networked with link modules.

2. The link axis function is an option that is available from SW 5 for NCU 573.2 in variants for 12 axes and 31 axes; it is required for each link axis (max. 32). It is determined by number.

3. The axis container function is an option that is available from SW 5 for NCU 573 12 axes/31 axes; it is required for each container. If a link module is employed, this function can be used without the additional option.

References: /PHD/, Configuring Guide NCU 571–573.2

3.4 Axis container

Availability

Axis container is an option that is available for the NCU 573.2 with SW 5 and higher. In cases where axis containers are configured for link axes, the supplementary conditions for such containers as defined in Section 3.3 “Link axes” also apply.
Notes
4.1 Machine data for several operator panels

The following machine data is provided for functions with SW 3.2 and higher:

<table>
<thead>
<tr>
<th>MD number</th>
<th>MD number</th>
<th>Description</th>
<th>Default Value</th>
<th>Min. Input Limit</th>
<th>Max. Input Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>10134</td>
<td>MM_NUM_MMC_UNITS</td>
<td>Resource units for MMC communications partners that are possible at the same time</td>
<td>6</td>
<td>1</td>
<td>10</td>
</tr>
</tbody>
</table>

(FM-NC: 4, NCUS71: 3, 810D: 3, MMC 100–103: 2, OP030: 1)

Changes effective after Power On: Protection level: 2 / 2; Unit: –

Data type: DWORD; Applies from SW version: 3.2

Significance:

- Number of simultaneously possible MMC communication partners with which the NCU can exchange data.
- The value influences how many communications jobs can be managed by the NC.
- The higher the value, the more MMCs can be simultaneously connected to the NC.
- Depending on the value entered in the machine data, DRAM is made available in the NCU for this function. Instructions regarding the modification of memory areas must be observed (see FB2/S7).
- The unit of MD 10134 is a resource unit.
- A standard OP030 requires 1 resource unit and an MMC 100/103 2. OEM variants may require more or fewer resources.

- Setting the value lower (than would normally be required by the number of connected MMCs) does not necessarily cause problems. Occasionally operations may not work if several communication-intensive operator actions (e.g., loading program) are being conducted at the same time: Alarm 5000 is displayed. The operator action must be repeated.
- If the value is set higher, more dynamic memory than necessary will be used up. If the memory is required for other purposes, the value should be reduced accordingly.
4.2 Machine data for link communication

4.2.1 General machine data

<table>
<thead>
<tr>
<th>MD number</th>
<th>AXCONF_LOGIC_MACHAX_TAB[n]</th>
</tr>
</thead>
<tbody>
<tr>
<td>List of machine axes available on an NCU (logical NCU machine axis image)</td>
<td></td>
</tr>
</tbody>
</table>

**Default value:** AX1, AX2, ..., AX31

**Min. input limit:** –

**Max. input limit:** –

**Changes effective after Power On:**

**Protection level:** 1 / 1

**Unit:** –

**Data type:** STRING

**Applies from SW version:** 5

**Significance:**

MD AXCONF_LOGIC_MACHAX_TAB maps channel axes on:

1. Local axes (default: AX1, AX2, ..., AX31)

   The entry $MN_AXCONF_LOGIC_MACHAX_TAB[n] = AX3$ assigns local axis AX3 to axis index n. (For n = 3 the default setting AX3 is available. Therefore MD blocks for Software Version 4 and lower are compatible in Version 5).

2. Link axes (axes that are physically connected to another NCU)

   The entry $MN_AXCONF_LOGIC_MACHAX_TAB[n] = NCj_AXi$ assigns axis AXi on NCU j to axis index n (link axis).

   **Limits:**
   
   - n: Machine axis address (of the local NCU) 1 ... 31
   - j: NCU number 1 ... 16
   - i: Machine axis address (of the local/remote NCU) 1 ... 31

3. Axis containers in which local or link axes are contained again.

   The entry $MN_AXCONF_LOGIC_MACHAX_TAB[n] = CTr_SLs$ assigns container r and slot s to axis index n.

   **Limits:**
   
   - n: Machine axis address (of the local NCU) 1 ... 31
   - r: Container number 1 ... 16
   - s: Slot number (location) in container 1 ... 32

**MD irrelevant for ...... Systems without link modules**

**Application example(s)**

Initial.ini (extract) on NCU3:

$MN_AXCONF_LOGIC_MACHAX_TAB[4] = NC5_AX7$

CHANDATA(2)

$MC_AXCONF_MACHAX_USED[1] = 5$

$MC_AXCONF_CHANAX_NAME_TAB[1] = MyAx_Y$

Part program block

"G0 MyAx_Y = 100" running on NCU3/channel 2 traverses the 7th axis of NCU 5.

**Related to .... AXCT_AXCONF_ASSIGN_TABi (create entries in containers i)**

<table>
<thead>
<tr>
<th>MD number</th>
<th>SERVO_FIFO_SIZE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Size of data buffer between interpolator and position control</td>
<td></td>
</tr>
</tbody>
</table>

**Default value:** 2

**Min. input limit:** 2

**Max. input limit:** 3

**Changes effective after Power On:**

**Protection level:** 3/2

**Unit:** –

**Data type:** DWORD

**Applies from SW version:** 5.2

**Significance:**

The MD specifies the size of the data buffer between the interpolator and position control. If several NCUs for rotary indexing machines/multi-spindle turning machines are connected via the NCU link, the value for all connected NCUs must be set to 3. This setting compensates for the difference in transmission time between local setpoints and setpoints from another NCU via the NCU link.
### 4.2 Machine data for link communication

#### 11398
**AXIS_VAR_SERVER_SENSITIVE**
Response of AXIS-VAR server to error condition

<table>
<thead>
<tr>
<th>MD number</th>
<th>Default value: 0</th>
<th>Min. input limit: 0</th>
<th>Max. input limit: 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Changes effective after Power On</td>
<td>Protection level: 2/7</td>
<td>Unit: –</td>
<td></td>
</tr>
<tr>
<td>Data type: BYTE</td>
<td>Applies from SW version: 5</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Significance:**
If the server cannot supply any values for an axis (e.g., because the axis concerned is a link axis), then it returns a default value (generally 0).

For the purpose of testing, this machine data can be used to set the axis data server sensitively so that it returns an error message rather than default values.

- 0: Default value
- 1: Error message

**MD irrelevant for:**
Systems without link modules

**Related to:**
MM_NCU_LINK_MASK

---

#### 12510
**NCU_LINKNO**
NCU number in an NCU group

<table>
<thead>
<tr>
<th>MD number</th>
<th>Default value: 1</th>
<th>Min. input limit: 1</th>
<th>Max. input limit: 16</th>
</tr>
</thead>
<tbody>
<tr>
<td>Changes effective after Power On</td>
<td>Protection level: 1 / 1</td>
<td>Unit: –</td>
<td></td>
</tr>
<tr>
<td>Data type: DWORD</td>
<td>Applies from SW version: 5</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Significance:**
Number of name for identifying an NCU within an NCU grouping.

In an NCU grouping (NCU cluster), the NCUs are interconnected via a link bus.

**MD irrelevant for:**
Systems without link modules

**Application:**
See Section 2 "Configuration of link axes"

**Related to:**
MM_NCU_LINK_MASK

---

#### 12520
**LINK_TERMINATION**
NCU numbers for which bus terminating resistors are active

<table>
<thead>
<tr>
<th>MD number</th>
<th>Default value: 0</th>
<th>Min. input limit: 0</th>
<th>Max. input limit: 15</th>
</tr>
</thead>
<tbody>
<tr>
<td>Changes effective after Power On</td>
<td>Protection level: 1 / 1</td>
<td>Unit: –</td>
<td></td>
</tr>
<tr>
<td>Data type: BYTE</td>
<td>Applies from SW version: 5</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Significance:**
LINK_TERMINATION defines for which NCUs the bus terminating resistors must be activated by the link module for the timing circuit.

**Related to:**
MM_NCU_LINK_MASK

---

#### 12530
**LINK_NUM_OF_MODULES**
Number of NCU link modules

<table>
<thead>
<tr>
<th>MD number</th>
<th>Default value: 2</th>
<th>Min. input limit: 2</th>
<th>Max. input limit: 16</th>
</tr>
</thead>
<tbody>
<tr>
<td>Changes effective after Power On</td>
<td>Protection level: 1 / 1</td>
<td>Unit: –</td>
<td></td>
</tr>
<tr>
<td>Data type: DWORD</td>
<td>Applies from SW version: 5</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Significance:**
The machine data specifies how many link modules are taking part in the link communication.

**MD irrelevant for:**
Systems without link modules

**Related to:**
MM_NCU_LINK_MASK
### 12540 LINK_BAUDRATE_SWITCH

<table>
<thead>
<tr>
<th>MD number</th>
<th>Link bus baud rate</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default value: 9</td>
<td>Min. input limit: 0</td>
</tr>
</tbody>
</table>

| Changes effective after Power On | Protection level: 1 / 1 | Unit: – |

| Data type: DWORD | Applies from SW version: 5 |

**Significance:** The values entered here define the baud rate assigned for the link communication:

**Set value** | **Rate**
---|---
0 | 9,600 Kbaud
1 | 19,200 Kbaud
2 | 45,450 Kbaud
3 | 93,750 Kbaud
4 | 187,500 Kbaud
5 | 500,000 Kbaud
6 | 1,500 Mbaud
7 | 3,000 Mbaud
8 | 6,000 Mbaud
9 | 12,000 Mbaud

**MD irrelevant for:** Systems without link modules

**Related to:** MM_NCU_LINK_MASK

### 12550 LINK_RETRY_CTR

<table>
<thead>
<tr>
<th>MD number</th>
<th>Maximum number of message frame repeats in event of error</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default value: 4</td>
<td>Min. input limit: 1</td>
</tr>
</tbody>
</table>

| Changes effective after Power On | Protection level: 1 / 1 | Unit: – |

| Data type: DWORD | Applies from SW version: 5 |

**Significance:** Maximum number of message frame repeats in event of error. If an error is detected during data transfer, the transmission can be repeated as often as specified in the MD.

<table>
<thead>
<tr>
<th>Baud rate</th>
<th>Recommended repetition value</th>
</tr>
</thead>
<tbody>
<tr>
<td>187,500 Kbaud</td>
<td>1</td>
</tr>
<tr>
<td>500,000 Kbaud</td>
<td>1</td>
</tr>
<tr>
<td>1,500 Mbaud</td>
<td>1</td>
</tr>
<tr>
<td>3,000 Mbaud</td>
<td>2</td>
</tr>
<tr>
<td>6,000 Mbaud</td>
<td>3</td>
</tr>
<tr>
<td>12,000 Mbaud</td>
<td>4</td>
</tr>
</tbody>
</table>

**MD irrelevant for:** Systems without link modules

**Related to:** MM_NCU_LINK_MASK
Machine data for link communication

**AXCT AXCONF ASSIGN TAB[1-16]**

**MD number**

List of axes in axis container 1, ..., 16

**Default value:** "" (empty string)

**Min. input limit:** –

**Max. input limit:** –

**Changes effective after Power On:**

**Protection level:** 7/2

**Unit:** –

**Data type:** STRING

**Applies from SW version:** 5

**Significance:** Assignment of an axis container slot (slot s) to a machine axis or link axis. Up to 32 slots can be assigned to axes in an axis container.

**Notation for entries:** NCm_AXn with NCU number m: 1...16 and machine axis address n: 1 ... 31

**Example:**
- NC2_AX1: The axis is on NCU2 where it is the 1st machine axis.
- AX5: Local axis 5 with only one NCU; the axis container mechanism is used only by more than one channel on an NCU.

The reference to an axis container slot of a channel is defined by machine data MD $MC AXCONF_MACHAX_USED and MD $MN AXCONF AXCONF_LOGIC_MACHAX_TAB.

The axis that is actually assigned at a specific time depends on the container rotation state. All channels that access an axis container use the entries stored here. If channels from different NCUs access this container, pay attention to consistency across the NCUs!

**Example:**
- CHANDATA(1)
  - $MN AXCONF LOGIC_MACHAX_TAB[8]=CT1 SL1
  - $MN AXCONF ASSIGN TAB[0]=NC1 AX1
  - $MN AXCONF ASSIGN TAB[1]=NC2 AX1

This machine data is distributed via the NCU link.

If $MA AXCONF ASSIGN_MASTER_CHAN is set for a container axis, then $MC AXCONF_MACHAX_USED in the assigned channel must refer to the entry in $MN AXCONF LOGIC_MACHAX_TAB. This contains a reference to the axis container slot to which this axis is assigned in the default setting. A power-up alarm is otherwise generated.

**Related to:** AXCONF LOGIC_MACHAX_TAB

**AXCONF_NAME_TAB**

**MD number**

List of axis container names

**Default setting:** "CT1", "CT2", ..., "CT16"

**Min. input limit:** –

**Max. input limit:** –

**Changes effective after Power On:**

**Protection level:** 1 / 1

**Unit:** –

**Data type:** STRING

**Applies from SW version:** 5.2

**Significance:** A name can be assigned to each axis container. The axis container rotation commands AXCTSWE and AXCTSWED can be used in conjunction with these names. If no container names are defined, channel axis names must be used (SW 5.1) which address the desired axis container via the logical machine axis image. This also applies to the addressing of system variables for axis containers.

The default axis container names are CT1, CT2, ..., CT16

**Application**

The name of the 1st axis container is AXCT1. Definition in MD:
- $MN AXCONF NAME TAB[0] = "AXCT1"
4.2 Machine data for link communication

### 18700 MM_SIZEOF_LINKVAR_DATA

- **MD number**: 18700
- **Size of the NCU link variable memory**
- **Default value**: 0
- **Min. input limit**: 0
- **Max. input limit**: 100
- **Changes effective after Power On**: Protection level: 7/2
- **Data type**: DWORD
- **Protection level**: Applies from SW version: 5
- **Significance**: Defines the number of bytes of link memory for NCU-global data.

### 18780 MM_NCU_LINK_MASK

- **MD number**: 18780
- **Activation of NCU link communication**
- **Default value**: 0
- **Min. input limit**: 0
- **Max. input limit**: 1
- **Changes effective after Power On**: Protection level: 1 / 1
- **Data type**: DWORD
- **Applies from SW version**: 5
- **Significance**: Activation of NCU link communication.
  - Bit-coded activation data (only 1 variant currently defined).
  - A value of 1 must be set to activate link communication.
  - (can be used for start-up of local axes [1:1], before link connections are powered up)
- **Related to**: IS_LOCAL_LINK_AXIS, NCU_LINK_NO, LINK_TERMINATION, LINK_NUM_OF_MODULES, LINK_BAUDRATE_SWITCH, LINK_RETRY_CTR

### 18790 MM_MAX_TRACE_LINK_PIONTS

- **MD number**: 18790
- **Size of trace data buffer for NCU link**
- **Default value**: 8
- **Min. input limit**: 0
- **Max. input limit**: 500
- **Changes effective after Power On**: Protection level: 1 / 1
- **Data type**: DWORD
- **Applies from SW version**: 5
- **Significance**: MM_MAX_TRACE_LINK_PIONTS defines the size of an internal data buffer containing the trace recordings for the NCU link functionality.
  - The MD is evaluated only if bit 0 is set in MM_TRACE_LINK_DATA_FUNCTION BIT 0.
- **Related to**: TRACE_SCOPE_MASK, MM_TRACE_DATA_FUNCTION, MM_MAX_TRACE_DATAPOINTS, TRACE_STARTTRAC_EVENT, TRACE_STARTTRAC_STEP, TRACE_STOPTRAC_EVENT, TRACE_STOPTRAC_STEP, TRACE_VARIABLE_NAME, TRACE_VARIABLE_INDEX, MM_TRACE_LINK_DATA_FUNCTION

### 4.2.2 Channel-specific machine data

### 28160 MM_NUM_LINKVAR_ELEMENTS

- **MD number**: 28160
- **Number of write elements for the NCU link variables**
- **Default value**: 0
- **Min. input limit**: 0
- **Max. input limit**: –
- **Changes effective after Power ON**: Protection level: 7/2
- **Significance**: –
4.2 Machine data for link communication

<table>
<thead>
<tr>
<th>28160</th>
<th>MM_NUM_LINKVAR_ELEMENTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>MD number</td>
<td>Number of write elements for the NCU link variables</td>
</tr>
<tr>

## 4.3 Setting data for link communication

### AXCT_SWWIDTH

<table>
<thead>
<tr>
<th>SD number</th>
<th>AXCT_SWWIDTH</th>
</tr>
</thead>
<tbody>
<tr>
<td>41700</td>
<td>Axis container rotation setting</td>
</tr>
</tbody>
</table>

- **Default value:** 1
- **Min. input limit:** 1
- **Max. input limit:** –
- **Changes effective after NewConfig:**
- **Protection level:** 3 / 3
- **Unit:** –
- **Data type:** BYTE

**Significance:** Setting specifying how many increments an axis container must rotate.

The SD is NCU-global.

As an axis container in which not only local axes are administered is NCU-global, in this case SD 41700 is also NCU-global. All NCU{s} whose axes appear in the axis container use the increment value stored here.

All channels that access an axis container use the increment value stored here.

If a value which is higher than the number of slots occupied in the relevant axis container is entered, the value is calculated modulo in relation to the number of occupied slots.

Unlike other setting data, a NEWCONF must be performed to refresh this setting data.
Signal Descriptions

5.1 Defined logical functions/Defines

---

**Note**

The specified values must be entered in the interface areas indicated in the tables below. The values must be checked to distinguish between the logical functions and results.

</table>
5.2 Interfaces in DB 19 for M:N

The MMC–PLC interface in DB19 is divided into 3 areas

Online request interface

The online request sequence is executed on this interface if an MMC wants to go online.

MMC writes its client ID to ONL_REQUEST and waits for the return of the client ID in ONL_CONFIRM.

After the positive acknowledgement from the PLC, the MMC sends its parameters and waits for online permission (in PAR_STATUS, PAR_Z_INFO).

MMC parameter transfer:

- Client identification  $\rightarrow$ PAR_CLIENT_IDENT
- MMC type  $\rightarrow$ PAR_MMC_TYP
- MCP address  $\rightarrow$ PAR_MSTT_ADR

With the positive online permission, the PLC also sends the number of the MMC–PLC online interface DBB109.4–7 to be used by the MMC.

The MMC then goes online and occupies the online interface assigned by the PLC.

Online interfaces

Two MMCs can be connected online to one NCU at the same time.

The online interface is available for each of the two online MMCs separately.

After a successful online request sequence, the MMC receives the number of its online interface from the PLC.

The MMC parameters are then transferred to the corresponding online interface by the PLC.

The MMC goes online and occupies its own online interface via which data are then exchanged between the MMC and PLC.

MMC data interfaces

User data from/to the MMC are defined on these:

- DBB 0–49  MMC1 interface
- DBB 50–99  MMC2 interface

These data and signals are always needed to operate MMCs.

M:N sign-of-life monitoring

This is an additional monitoring function which must not be confused with the MMC sign-of-life monitor. For further information, please refer to the relevant signals.
In certain operating states, MMCs with activated M:N switchover (parameterizable in NETNAMES.INI) must be capable of determining from a PLC data whether they need to wait or not before linking up with an NCU.

Example:
MMC with an activated control unit switchover function must be capable of starting up an NCU without issuing an online request first.

MMC must go online for service-related reasons.

The operation is coordinated in the online request interface via data DBW110: M_TO_N_ALIVE

The M:N sign of life is a ring counter which is incremented cyclically by the PLC or set to a value of 1 when it overflows.

Before an MMC issues an online request, it must check the sign of life to establish whether the M:N switchover is activated in the PLC.

Procedure:
MMC reads the sign of life at instants T0 and T0 + 1.

Case 1: Negative acknowledgement for read operation, DB19 does not exist. MMC goes online without prior online request

Case 2: m_to_n_alive = 0
Control unit switchover not activated.
MMC goes online without prior online request

Case 3: m_to_n_alive (T0) = m_to_n_alive (T0+1)
Control unit switchover not activated
MMC goes online without prior online request.

Case 4: m_to_n_alive (T0) <> m_to_n_alive (T0+1)
Control unit switchover activated

Cases 1 to 3 apply only under special conditions and not in normal operation.

### Online request interface

<table>
<thead>
<tr>
<th>No.</th>
<th>Name</th>

<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>MPI 1 or</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>MCP 2</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Bit 0 .. 7:</td>
<td>MMC bus address</td>
<td></td>
</tr>
</tbody>
</table>
### DB19 DBW102 ONL_CONFIRM

**Client_Ident**

If the online request interface is not being used by another MMC, the PLC returns the Client identification as positive acknowledgement.

<table>
<thead>
<tr>
<th>Bit 8 .. 15:</th>
<th>Bus type:</th>
</tr>
</thead>
<tbody>
<tr>
<td>MPI</td>
<td>1</td>
</tr>
<tr>
<td>MCP</td>

<th>Bus type:</th>
</tr>
</thead>
<tbody>
<tr>
<td>MPI</td>
<td>1</td>
</tr>
<tr>
<td>MCP</td>
<td>2</td>
</tr>
</tbody>
</table>

| Bit 0 .. 7: | MMC bus address |

### DB19 DBB106 PAR_MMC_TYP MMC parameter transfer to PLC

**MMC type from NETNAMES.INI**

Type properties of the MMC configured in file NETNAMES.INI. Evaluated by the PLC when MMC is suppressed (server, main/secondary operator panel, ...), see description of file NETNAMES.INI.

### DB19 DBB107 PAR_MSTT_ADR MMC parameter transfer to PLC

**MCP address from NETNAMES.INI**

Address of MCP to be switched over or activated/deactivated with the MMC. Parameter from NETNAMES.INI.

| 255 | No MCP is assigned to MMC, no MCP will be activated/deactivated |

### DB19 DB108 PAR_STATUS PLC sends MMC pos./neg. online permission

**ONL_PERM (5)**

PLC notifies MMC as to whether it can go online or not. The meaning of the signal is dependent on PAR_Z_INFO:

#### ONL_PERM (5)

| Bit 0 .. 3: OK |
| Bit 4 .. 7: No. of the MMC – PLC online interface to which MMC must be connected: |
| 1 | First MMC – PLC online interface |
| 2 | Second MMC – PLC online interface |

**MMC_LOCKED (13)**

The requesting MMC cannot go online. Two MMCs on which uninterruptible processes are in progress are connected online to this NCU. The PLC cannot suppress either of the two MMCs.

**PLC_LOCKED (14)**

The MMC switchover disable is set in the MMC – PLC interface.

**PRIO_H (15)**

The requesting MMC cannot go online. Two MMCs that are both higher priority than the requesting MMC are connected online to the NCU. The PLC cannot suppress either of the two MMCs.

### 2. MMC–PLC online interface

The signals of the 2nd MMC–PLC online interface are analogous in meaning to the signals of the 1st MMC–PLC online interface. MMC2_... replaces MMC1_... in the explanatory texts.
After an MMC has gone online to an NCU, the MMC sign of life is set in the interface. (E_BTSSReady, E_MMCMPI_Ready, E_MMC2Ready)

The signals are automatically set by the MMC when it goes online and stay set for as long as it remains online.

They are provided separately for each MMC–PLC interface and used by the PLC to monitor the MMC sign of life.

### 1. MMC–PLC online interface

A distinction between an MMC link via the OPI (1.5 Mbaud) or the MPI (187.5 kbaud) is made on this interface.

The signal corresponding to the bus type is set while the MMC is online.

### 2nd MMC–PLC online interface

This interface utilizes a group signal for both bus types. No distinction is made between OPI and MPI.

<table>
<thead>
<tr>
<th>DB10</th>
<th>DBX108.1</th>
<th>E_MMCM2Ready</th>
</tr>
</thead>
<tbody>
<tr>
<td>FALSE</td>
<td>No MMC online to OPI or MPI</td>
<td></td>
</tr>
<tr>
<td>TRUE</td>
<td>MMC online to OPI or MPI</td>
<td></td>
</tr>
</tbody>
</table>

The sign-of-life monitor is switched on by the PLC as soon as an MMC has gone online to its interface and switched off again when it goes offline.

Sign-of-life monitor is **switched on**:

- As soon as an MMC logs on online to its MMC–PLC interface with S_ACT/ CONNECT.
Sign-of-life monitor is switched off:

- As soon as MMC goes offline

1. MMC wants to switch over and logs off from the PLC with
   OFFL_REQ_OP/ OK
   PLC acknowledges the MMC with OFFL_CONF_OP/ OK
2. MMC is suppressed by the PLC with OFFL_REQ_PLC/ OK
   MMC acknowledges the PLC with OFFL_CONF_PLC/ OK

In both instances the PLC detects that an MMC is going offline and waits for the TRUE–FALSE edge of its sign-of-life signal.

The PLC then ceases to monitor the sign-of-life signal.

6.2 User-specific re-configuring of PLC program “Control unit switchover”

**Introduction**

The solution outlined roughly below should be selected only if at least one of the following configuring requirements is applicable:

- Displacement strategy which differs from standard functionality
- Operating mode switchover which differs from standard functionality
- Independent handling of override switch for switchover of control unit
- Existence of a 2nd machine control panel on an MMC

Method of description:

1. Description of operational sequences
2. Description of available functionality (Defines)
3. Graphic representation of sequences in diagrammatic form

Implementation details can also be obtained from the standard configuration which is included in the toolbox.
6.2.1 Description of operational sequences (overview)

Overview:

MMC sends online request  An MMC would like to link up with an NCU and sends this request to the PLC of the relevant NCU.

MMC arrives  An MMC goes online to an NCU, i.e. it links up to the NCU.

MMC goes  An MMC breaks off the link to an NCU.

Displacement  An MMC must abort the link with an NCU because another MMC wants to go online to the same NCU.

Operating focus changeover in server mode  A server maintains a permanent link to the NCUs to which it is assigned. The operator can switch the operating focus from one NCU to another without interrupting the existing link.

Active/passive operating mode  An online MMC can operate in two different modes:

Active mode: Operator can operate and monitor
Passive mode: Operators sees header information and the “passive” identifier.

MCP switchover  As an option, an MCP assigned to the MMC can be switched over at the same time as the MMC.
6.2.2 Description of operational sequences (details)

Introduction

The operational sequences are described using identifiers for defined, logical functions (example: OFFL_REQ_OP/OK) whose programming application has been described earlier in this section. The functions are coded according to Section 5.1. The functions store values in the interface which can be addressed from the PLC and the MMC. An MMC utilizes the online-request interface while it competing for the use of an online interface. MMCS which are already linked to an NCU utilize one of the two available online interfaces. Details of these interfaces can be found in Chapter 5 and in References:

References: Lists

In order to illustrate complete operating sequences, the description covers MMC activities which cannot be influenced as well as modifiable PLC activities.

MMC sends online request

If the MMC is already linked online to an NCU (online NCU) and would like to communicate with another NCU (target NCU), it must first notify the PLC of the online NCU that it wishes to switch over to the target NCU.

It sends the offline request OFFL_REQ_OP/OK to the online PLC.

OFFL_CONF_OP/OK:

Online PLC has received the offline request. MMC can now send an online request to the target PLC.

OFFL_CONF_OP/PLC_LOCKED

Online PLC has received the offline request. The MMC switchover is disabled in the MMC–PLC interface. The MMC cannot link up with another NCU and must remain online.

On receipt of the positive acknowledgement OFFL_CONF_OP/OK, the MMC sends its online request to the target PLC of the relevant NCU by transmitting its client identification.

Client identification: Unique MMC identifier comprising bus type and MMC bus address. (ONL_REQUEST DB19, DBW100)

The target PLC sends the MMC a positive or negative acknowledgement:

Pos. acknowledgement: Target PLC returns the client identification to the MMC. (ONL_CONFIRM, DB19, DBW102)

MMC sets its parameters on the online-request interface.

Neg. acknowledgement: Target PLC does not return the client identification to the MMC. (ONL_CONFIRM, DB19, DBW102 not identical to client identification of requesting MMC).

MMC cannot go online.
6.2 User-specific re-configuring of PLC program “Control unit switchover”

Example:
Another MMC is currently switching over to the same NCU. This switchover operation must not be interrupted. The MMC remains online to the online NCU.

Once the MMC has received positive acknowledgement from the PLC, it may need to displace another online MMC. It will then receive positive/negative online permission from the PLC.

Positive:
ONL_PERM/ OK

On receipt of positive online permission (DB 19, DBB 108, 109), the MMC can go online. An MMC–PLC interface is allocated to the MMC at the same time as online permission. (1 or 2, details can be found in the interface description in Chapter 5).

Negative:
ONL_PERM/ MMC_LOCKED

The requesting MMC cannot go online. Two MMCs currently executing uninterruptible processes are linked online to this NCU. The PLC cannot displace either of the two MMCs. The MMC remains online to the online NCU.

ONL_PERM/ PLC_LOCKED

The requesting MMC cannot go online. The MMC switchover is disabled in the MMC–PLC interface. The MMC remains online to the online NCU.

ONL_PERM/ PRIO_H

The requesting MMC cannot go online. Two MMCs that are both higher priority than the requesting MMC are connected online to the NCU. The PLC cannot displace either of the two MMCs. The MMC remains online to the online NCU.

MMC arrives

Once the MMC has sent an online request to the target PLC and received online permission from it, it can set up a link to the target NCU.

It goes online and notifies the PLC with (station active) S_ACT/ CONNECT that it has linked up with the NCU.

The MMC sets up its sign of life signal in accordance with the allocated interface.

The MMC then requests
in the case of operator panel: Active operating mode on the target NCU or
in the case of a server: Operating focus on the target NCU.

The PLC then activates MMC sign-of-life monitoring for the new MMC.

See: Active/passive operating mode
See: Operating focus changeover in server mode
6.2 User-specific re-configuring of PLC program “Control unit switchover”

**MMC goes**

An MMC aborts communication with an NCU.

Communication can be aborted for two different reasons:

1. The operator wishes to switch the MMC to another NCU. The MMC has send an online request to the target PLC and received online permission (ONL_PERM/ OK). It has notified the online PLC of its intention to switch over with OFFL_REQ_OP/ OK and received a positive acknowledgement (OFFL_CONF_OP/ OK). Due to the switchover to the target NCU, the MMC sign of life in the online PLC is changed from TRUE to FALSE. The falling edge combined with the sequence described above signals to the online PLC that the MMC has broken off the link to the online NCU. If an MCP is assigned to the MMC and activated, it is now deactivated by the PLC. Passive operating mode is set in the PLC for the MMC which has gone offline.

   See: Active/passive operating mode

2. The MMC is excluded (displaced) from the PLC by the online request from another MMC. See displacement.

**Displacement**

Two MMCs are linked online to an NCU, each is occupying an MMC–PLC interface. A third MMC would like to go online.

The PLC must displace one of the two MMCs according to a predefined strategy.

It requests the MMC to be displaced to abort communication with the NCU by sending it the offline request (OFFL_REQ_OP/ OK).

The MMC returns a positive or negative acknowledgement to the PLC:

Positive:

OFFL_CONF_PLC/ OK

MMC breaks off the link to the NCU and switches to the offline state.

The MMC sign of life in the PLC changes from TRUE to FALSE.

The falling edge combined with the sequence described above signals to the online PLC that the MMC has broken off the link to the online NCU.

If an MCP is assigned to the MMC and activated, it must now be deactivated by the PLC.

The PLC also ceases to monitor the MMC sign of life signal.

Passive operating mode is set in the PLC for the MMC which has been displaced.

See “Active/passive operating mode” further below.

Negative:

OFFL_CONF_PLC/ MMC_LOCKED

The MMC is executing processes which cannot be interrupted (e.g. operation via V.24 interface, data exchange between NCU and MMC).

The MMC remains online to the current NCU.
6.2 User-specific re-configuring of PLC program "Control unit switchover"

**Operating focus changeover in server mode**

A server maintains a permanent link to the NCUs to which it is assigned. The operator can switch the operating focus from one NCU to another without interrupting the existing link.

If the operator wishes to switch the operating focus to another NCU, the focus PLC and target PLC must first be interrogated to determine whether they will permit a focus switchover.

The MMC first sends the focus offline request signal (OFFL_REQ_FOC/OK) to the focus PLC.

The focus PLC returns either a positive or negative acknowledgement to the MMC:

**Positive:**

OFFL_CONF_FOC/OK

PLC positively acknowledges the focus offline request. MMC can disconnect the operating focus.

**Negative:**

OFFL_CONF_FOC/PLC_LOCKED

PLC negatively acknowledges the online focus request. The operating focus changeover is disabled in the MMC–PLC interface (same signal as for MMC switchover disable). The operating focus remains on the current NCU.

After a positive acknowledgement (OFFL_CONF_FOC/OK) from the focus PLC, the MMC sends query signal ONL_REQ_FOC/OK regarding focus changeover to the target PLC.

The target PLC returns a positive or negative acknowledgement to the MMC:

**Positive:**

ONL_PERM_FOC/OK

PLC positively acknowledges the focus offline request. MMC can disconnect the operating focus.

**Negative:**

ONL_PERM_FOC/PLC_LOCKED

PLC negatively acknowledges the focus offline request. The operating focus changeover is disabled in the MMC–PLC interface (same signal as for MMC switchover disable). The operating focus remains on the current NCU.

After the MMC has received permission from the target PLC to change the operating focus (ONL_PERM_FOC, OK), the MMC logs off from the focus PLC with S_ACT/DISC_FOCUS and changes the focus to the target PLC.

The MMC must finally request active operating mode in the target NCU. The previous focus PLC must set active operating mode for this MMC–PLC interface after receiving S_ACT/DISC_FOCUS and deactivate any active MCP assigned to the MMC which has gone offline.

See: Active/passive operating mode

**Active/passive operating mode**

After an MMC has gone online to an NCU, it can assume one of two different operating states:

**Active mode:** Operator can operate and monitor
Passive mode: Operators sees header information and the “passive” status identifier.

After switching to an NCU, it first requests active operating mode in the online PLC.

If two MMCs are linked online simultaneously to an NCU, one of the two is always in active mode and the other in passive mode.

The operator can request active mode on the passive MMC by pressing a key.

If an MCP has been configured for the online MMCs, the MCP of the active MMC is switched on.

The MCP of the passive MMC is deactivated, i.e. only one MCP is active at a time on an NCU.

Four signals are provided in the MMC–PLC interface for each of the two online MMCs. These signals are used by the PLC to control operating mode changeovers.

Table 6-1 Signals (x = 1, 2: 1st or 2nd MMC–PLC interface)

<table>
<thead>
<tr>
<th>MMC–PLC interface</th>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>

<td></td>
<td>TRUE-&gt;FALSE</td>
<td>MMC to PLC or PLC to MMC depending on interface: Acknowledgment of MMCx_CHANGE_DENIED(FALSE-&gt;TRUE)</td>
</tr>
</tbody>
</table>

An example of how operating modes can be switched over is described in the following sequence.

Two MMCs online to one NCU, MMC_1 in active operating mode, MMC_2 in passive operating mode, operator requests active operating mode on MMC_2.

These sequence applies equally to the following cases:

- An MMC goes online to an NCU to which another MMC is linked online and in active mode. It requests active operating mode.
- An MMC goes online to an NCU to which no other MMC is linked online. It requests active operating mode. (The sequence “PLC requests active MMC to switch to passive operating mode” is not included here).
6.2 User-specific re-configuring of PLC program “Control unit switchover”

Signal state for this case:

Table 6-2

<table>
<thead>
<tr>
<th>MMC_1</th>
<th>VALUE</th>
<th>MMC_2</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>MMC1_ACTIVE_REQ</td>
<td>FALSE</td>
<td>MMC2_ACTIVE_REQ</td>
<td>FALSE</td>
</tr>
<tr>
<td>MMC1_ACTIVE_PERM</td>
<td>TRUE</td>
<td>MMC2_ACTIVE_PERM</td>

<td>TRUE</td>
<td>MMC2_ACTIVE_CHANGED</td>
<td>FALSE</td>
</tr>
<tr>
<td>MMC1_CHANGE_DENIED</td>
<td>FALSE</td>
<td>MMC2_CHANGE_DENIED</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

MMC_2 requests active operating mode and sets MMC_2_AKTIVE_REQ = TRUE.

The PLC acknowledges the request from MMC_2 with MMC_2_ACTIVE_REQ = FALSE.

The PLC then requests MMC_1 to change to passive operating mode with MMC1_ACTIVE_PERM = FALSE.

MMC_1 can respond to this request in two different ways:

1. MMC_1 can change to passive operating mode:
   MMC_1 switches from active to passive operating mode and acknowledges the changeover with MMC1_ACTIVE_CHANGED = FALSE.
   If an MCP is assigned to the MMC and activated, it is now deactivated by the PLC.
   The PLC notifies MMC_2 that it can change to active operating mode by sending MMC2_ACTIVE_PERM = TRUE.
   MMC_2 changes state and acknowledges the change with MMC2_ACTIVE_CHANGED = TRUE. If an MCP is assigned to MMC_2, it is now activated by the PLC.

2. MMC_1 cannot change to passive mode (processes which cannot be interrupted are in progress on MMC_1):
   MMC_1 sets MMC1_CHANGE_DENIED = TRUE, operating status cannot be changed.
   The PLC acknowledges with MMC1_CHANGE_DENIED = FALSE and grants MMC_1 permission to remain in active mode with MMC1_ACTIVE_PERM = TRUE. By sending MMC2_CHANGE_DENIED = TRUE, it notifies MMC_2 that MMC_1 cannot switch over to passive mode.
   MMC_2 then acknowledges with MMC2_CHANGE_DENIED = FALSE and remains in passive operating mode.
6.2 User-specific re-configuring of PLC program “Control unit switchover”

Please note: The arrangement of the signals of a box in box PLC_x (marked as B) corresponds to the arrangement of signal names in the header section (marked as A). Blocks B repeat in box PLC_x from top to bottom as a function of time.
MMC_1 requests active mode, MMC_2 is in active mode, can change to passive mode

<table>
<thead>
<tr>

</tbody>
</table>

**MMC_1**
- MMC_1 requests active operating mode
- MMC_1 waits for acknowledgement
- MMC_1 waits for active permission
  - MMC_1 receives: Change not allowed
  - MMC_1 remains in passive mode

**PLC_1**
- PLC_1 acknowledges, cancels active mode for MMC_2

**MMC_2**
- MMC_2 receives passive request: None
- Change to passive mode not allowed, uninterruptible processes in progress
- MMC_2 remains active
- PLC_1 to MMC_2: MMC_2 remains active
- PLC_1 to MMC_1: Change not allowed

Fig. 6-3 MMC_1 requests active mode, MMC_2 is in active mode, but cannot change to passive mode
A control unit consists of an MMC and an MCP; these can both be switched over as a unit.

If an MCP has been configured for the MMC in configuring file NETNAMES.INI, it will be activated and deactivated with the MMC.

The MCP of whichever MMC is currently in active operating mode is activated.

In other words, only one MCP is ever active at any time on an NCU.

The MCP is activated by the PLC:

- MMC changes to active operating mode. (signal MMCx_ACTIVE_CHANGED: FALSE -> TRUE, x = 1,2 first or second MMC–PLC interface)

The MCP is deactivated by the PLC

- MMC changes to passive operating mode (signal MMCx_ACTIVE_CHANGED: TRUE -> FALSE, x = 1,2 first or second MMC–PLC interface)
- MMC goes offline as a result of switchover or displacement
  The MMC sign-of-life signal changes from TRUE to FALSE when an MMC goes offline. After the edge change, the PLC deactivates the allocated MCP.
- Server MMC disconnects operating focus from the current NCU and switches it over to another. The server transmits S_ACT/DIS_FOCUS as the last signal on its own MMC–PLC interface. The PLC then deactivates the corresponding MCP.
6.2.3 Defined logical functions/Defines

Note
Please refer to Section 5.1 for the legal values for bus type, functions/status and additional information plus permissible combinations of status and additional information. The logical identifiers of functions are used in the following diagrams.
### 6.2.4 Graphic representation of function sequences

**Overview**

Figs. 6-4 to 6-9 describe the switchover operation for an operator station and Figs. 6-10 to 6-12 the switchover operation for a server.

The diagrams describe how an operator station is switched over (switchover from NCU_1 to NCU_2).

If an MMC in the offline status wishes to go online to an NCU (e.g. during power-up), sequence OFFL_REQ_OP(...) and OFFL_CONF_OP(...) is omitted.

---

**Fig. 6-4**

MMC_1 is linked online to NCU_1 and wants to switch over to NCU_2, switchover disable is set in PLC_1.
6.2 User-specific re-configuring of PLC program “Control unit switchover”

6.3 Configuration file NETNAMES.INI, standard functionality

6.3.1 Two operator panels and one NCU

For a system according to SW 3.1 (consisting of two control units and one NCU on the OPI, see Chapter 1), a sample configuration file for the second control unit is detailed below. For explanations, see Chapter 1 "Configurability".

```
; NETNAMES.INI example 2 start

; Identification division
[own]
owner = MMC_2

; Connection division
[conn MMC_1]
conn_1 NCU_1

[conn MMC_2]
conn_1 NCU_1

; Description division
[param network]
bus = opi

[param MMC_1]
mmc_address = 1

[param MMC_2]
mmc_address = 3

[param NCU_1]
nck_address = 13
plc_address = 13

; NETNAMES.INI example 2 end
```
6.3.2 One operator panel and three NCUs

For a system according to SW 3.2 (consisting of one control unit and three NCUs on the OPI, see Chapter 1, paragraph “Configurability”), a sample configuration file is detailed below.

For explanations, see Chapter 1, paragraph “Configurability”.

Any adaptations which may need to be made are described in Chapter 2, paragraph “Configurations”.

; NETNAMES.INI, example 3 start
; Identification division:
[own]
owner= MMC_1

; Connection division: For a maximum of 3 connections intended
[conn MMC_1]
conn_1= NCU_1
conn_2= NCU_2
conn_3= NCU_3

; Description division: The network is defined unambiguously
[param network]
bus= opi

[param MMC_1]
name= arbitrary_name
type= MMC_100
mmc_address= 1

[param NCU_1]
name= arbitrary_name1
type= ncu_572
nck_address= 12
plc_address = 12

[param NCU_2]
name= arbitrary_name2
type= ncu_573
nck_address= 14
plc_address= 14

[param NCU_3]
name= arbitrary_name3
type= ncu_573
nck_address= 15
plc_address= 15

; NETNAMES.INI, example 3 end
6.4 Link axis

Assumption
NCU1 and NCU2 have one link axis each, machine data e.g.:

; Machine data of NCU1:
$MN_NCU_LINKNO = 1 ; Set NCU number to 1
$MN_MM_NCU_LINK_MASK = 1 ; (master NCU)
$MN_SERVO_FIFO_SIZE = 3 ; Size of data buffer
$MN_MM_LINK_NUM_OF_MODULES = 2 ; Number of interpolation
 ; and servo loop
$MN_MM_LINK_NUM_OF_MODULES = 2 ; Number of link modules

$MN_AXCONF_LOGIC_MACHAX_TAB[0] = "AX1"
$MN_AXCONF_LOGIC_MACHAX_TAB[1] = "AX2"
$MN_AXCONF_LOGIC_MACHAX_TAB[2] = "NC2_AX3" ; Link axis

; Unique NCU axis names
$MN_AXCONF_MACHAX_NAME_TAB[0] = "NC1_A1"
$MN_AXCONF_MACHAX_NAME_TAB[1] = "NC1_A2"
$MN_AXCONF_MACHAX_NAME_TAB[2] = "NC1_A3"

CHANDATA(1)
$MC_AXCONF_MACHAX_USED[0] = 1
$MC_AXCONF_MACHAX_USED[1] = 2
$MC_AXCONF_MACHAX_USED[2] = 3
...

; Machine data of NCU2:
$MN_NCU_LINKNO = 2 ; Set NCU number to 2 (slave NCU)
$MN_MM_NCU_LINK_MASK = 1
$MN_SERVO_FIFO_SIZE = 3
$MN_MM_LINK_NUM_OF_MODULES = 2

$MN_AXCONF_LOGIC_MACHAX_TAB[0] = "AX1"
$MN_AXCONF_LOGIC_MACHAX_TAB[1] = "AX2"
$MN_AXCONF_LOGIC_MACHAX_TAB[2] = "NC1_AX3" ; Link axis

; Unique NCU axis names
$MN_AXCONF_MACHAX_NAME_TAB[0] = "NC2_A1"
$MN_AXCONF_MACHAX_NAME_TAB[1] = "NC2_A2"
$MN_AXCONF_MACHAX_NAME_TAB[2] = "NC2_A3"

CHANDATA(1)
$MC_AXCONF_MACHAX_USED[0] = 1
$MC_AXCONF_MACHAX_USED[1] = 2
$MC_AXCONF_MACHAX_USED[2] = 3
6.5 Axis container coordination

The characteristic as a function of time is displayed from top to bottom in the following tables. The data are valid on condition that only two channels have axes in the container.

6.5.1 Axis container rotation without a part program wait

<table>
<thead>
<tr>
<th>Channel 1</th>

6.7 Configuration of a multi-spindle turning machine

Introduction

The following example describes the use of:

- Several NCUs in the NCU link group
- Flexible configuration with axis containers

Machine description

- Distributed on the circumference of a drum A (front-plane machining) the machine has:
  - 4 main spindles HS1 to HS4
    Each main spindle has the possibility of material feed (bars, hydraulic bar feed, axes: STN1–STN4).
  - 4 cross slides
  - Each slide has two axes.
  - Optionally a powered tool S1–S4 can operate on each slide.
- Distributed on the circumference of a drum B (rear-plane machining) the machine has:
  - 4 counterspindles GS1 to GS4
  - 4 cross slides
  - Each slide has two axes.
  - Optionally a powered tool S5–S8 can operate on each slide.
  - The position of each counterspindle can be offset through a linear axis for example for transferring parts from the main spindle for rear-plane machining in drum B. (Transfer axes. Axes ZG1–ZG4).

- Links:
  - If drum A rotates, all main spindles of this drum are subordinate to another group of slides.
  - If drum B rotates, all main counterspindles and all transfer axes of this drum are subordinate to another group of slides.
  - Rotations of drums A and B are autonomous.
  - Rotations of drums A and B are limited to 270°. (range and torsion of supply lines)

Term: Position

Main spindle HS_i and counterspindle GS_i together with their slides characterize a position.
NCU assignment

The axes and spindles of a position (for this example) are each assigned to an NCU. One of the NCUs, the master NCU, controls the axes for the rotations of drums A and B additionally. There are 4 NCUs with a maximum of the following axes:

Axis number

Per NCUi the following axes/spindles must be configured:
- Slides: \(X_i, Z_i\)
- 1: \(X_1, Z_1\)
- 2: \(X_2, Z_2\)
- Spindles: \(H_{Si}, G_{Si}\), powered tools: \(S_1, S_2\)
- Transfer axis: \(Z_{Gi}\)
- Bar feed: \(STN_i\)

For the master NCU, in addition to the above-mentioned axes there are the two axes for rotating drums A and B. The list shows that it would not be possible to configure the axis number for a total of 4 positions via an NCU. (Limit 31 axes, required are \(4 + 10 + 2\) axes).

Axis container

With rotation of drums A/B, \(H_{Si}, G_{Si}, Z_{Gi}\) and \(STN_i\) must be assigned to another NCU and must therefore be configured as link axes in axis containers.

Fig. 6-13 Main spindles \(H_{Si}\), countersp. \(G_{Si}\), bar infeed axis \(STN_i\) and transfer axes \(Z_{Gi}\) diagrammatic
Fig. 6-14 Two slides per position can also operate together on one spindle.

**Note**

For clarifying the assignment of axes to slides and positions, the axes are named as follows:

- $X_{ij}$ with $i$ slide (1, 2), $j$ position (A–D)
- $Z_{ij}$ with $i$ slide (1, 2), $j$ position (A–D)

Positions and their slides remain in a fixed position, whereas main spindles, counterspindles, bar feed axes STN and transfer axes ZG move to new positions by rotation of drums V or H.
For example, the axes to be managed per NC when the slide is taken into account are as follows for the configurations shown in the foregoing illustrations:

### Axes of the master NCU

<table>

<td></td>
</tr>
</tbody>
</table>

### Axes of NCUb to NCUd

The NCU's that are not master NCU's have the same axes with the exception of the axes for the drive for drums TRV and TRH. The letter characterizing the position must be replaced accordingly for NCU and axis name (a, A → b, B to d, D).

### Configuration rules

The following rules were applied for the configuration described below:

- Main spindle, counterspindles and axes that are assigned to different NCU's through drum rotation while they are operating as illustrated in the above Fig. "Main spindle ..." must be configured in an axis container. (HSi, GSi, ZGi, STNi).
- All main spindles for drum A are in the same container (No. 1).
- All bar feed axes for drum A are in the same container (No. 2).
- All counterspindles for drum B are in the same container (No. 3).
- All transfer axes for drum B are in the same container (No. 4).
- Main spindles HS1 and their counterspindle GSi as well as the transfer axes for counterspindle ZGi and the bar feed axes STNi of the main spindle are assigned as follows for uniform load distribution purposes:
  - NCUa HS1 – STN1,
  - NCUb HS2 – STN2, ... etc.
- Slide axes Xij, Zij are solely local axes with a fixed NCU assignment.
6.7 Configuration of a multi-spindle turning machine

- Slides are all assigned to a separate channel on an NCU. Thus slides can be moved autonomously.

**Configuration possibilities**

- Main or counterspindles are flexibly assigned to the slide.
- In each position the main spindle and counterspindle spindle speed can be determined independently.

**Exceptions:**

During part change from front-plane machining in drum V to rear-plane machining in drum H, the main spindle and counterspindle must be brought to the same spindle speed (synchronous spindle coupling).

If slide 2 is also active in front-plane machining to “support” slide 1, in this case the main spindle speed is also valid for slide 2. Accordingly, if slide 1 is active in rear-plane machining, the counter spindle speed is also applicable for slide 1.

**Small changes in speed**

Owing to the unavoidable time delays incurred in the processing of actual values, abrupt changes in speed should be avoided during cross-NCU machining operations. Compare axis data and signals.

**Configuration for NCU1**

Uniform use of channel axis names in the part programs:

- S4 main spindle
- S3 counterspindle
- X1 infeed axis
- Z1 longitudinal axis
- S1 powered tool
- Z3 transfer axis
- TRV drum V for main spindle
- TRH drum H for counterspindle
- STN hydraulic bar feed

Axes highlighted in **bold** characterize the current channel as home channel for the axis in conjunction with axis exchange.

<td></td>
<td></td>
</tr>
</tbody>
</table>

**Note**

- * due to program coordination via axis positions and 4-axis machining in one position
- Entries in the axis container locations should have the following format: "NC1_AX.." required with the meaning NC1 = NCU 1. In the above tables, NCUs is imaged on NC1_..., NCUb on NC2_... etc.
Further NCUs

The above listed configuration data must be specified accordingly for NCUb to NCUd. Please bear the following in mind:

- Axes TRA and TRB only exist for NCUa, channel 1.
- The container numbers are maintained for the other NCUs as they were specified for the individual axes.
- The slot numbers are:
  - NCUb → 2
  - NCUc → 3
  - NCUd → 4.
- The machine axis names are:
  - NCUb → HS2, GS2, ZG2, STN2
  - NCUc → HS3, GS3, ZG3, STN3
  - NCUd → HS4, GS4, ZG4, STN4.

Axis containers

The information relating to containers given in Table 6-4 and the container entries of the similarly configured NCUs, NCUb to NCUd, are specified in the following tables, sorted according to containers and slots, as they have to be set in machine data:

```markdown
MD 12701: $MN_AXCT_AXCONF_ASSIGN_TAB1[slot]
```

```markdown
MD 12716: $MN_AXCT_AXCONF_ASSIGN_TAB16[slot]
```

with slots: 1 – 4 for the 4 positions of a multi-spindle turning machine.

Note

For the MD entry $MN_AXC_AXCONF_ASSIGN_TAB[slot], the values (without decimal point and machine axis name) that are entered under initial position in the above tables must be set.

Brief Description

Applications

The “Operation via PG/PC” functionality

- must be utilized if no operator panel is installed.
- can be utilized as a handling support for OP030 panels

Hardware

The following HW requirements must be fulfilled:

- PG/PC with at least 486DX33 processor and 8 MB main memory
- ENHANCED mode (386 mode) operation of MS WINDOWS must be available
- PG/PC with MPI/OPI interface (provided with PG 720/720C/740/760). An MPI card (6ES7793-2AA00-0AA0) is available for PCs with free ISA slot.
- VGA monitor with a resolution of 640x480 or higher.

Implementation with SW 3.1 and higher

The option of creating a link between two operator panels and one NCU has been implemented in SW 3.1. The machine control panel MCP is permanently allocated to the NCU.

Fig. 1-1 Configuration with OP030 and PG/PC or MMC 102/103

All operator panels and the NCU are either connected to the OPI bus or all to the MPI bus. A homogeneous network must be provided with respect to these components.
Implementation with SW 3.2 and higher

From SW 3.2, an additional option of linking one operator panel and up to three NCU's is implemented. The machine control panel is permanently allocated to the relevant NCU.

![Diagram]

Fig. 1-2  Configuration in SW 3.2 m:n corresponds to 1 : 3

References:  [FB2], B3, "Several Operator Panels and NCUs"

Software installation

see Chapter 2

User interfaces

The user interfaces are described in the Operator’s Guides of the relevant operator panels.

References:  [BA], Operator’s Guide
[FB2, OP 030 Operator’s Guide]

Restrictions

If the "Operation via PG/PC" functionality is used in addition to an OP030 operator panel, the conditions relating to configuration and coordination described in [FB2], B3, "Several operator panels and NCUs" must be observed.

References:  [FB2], B3, "Several Operator Panels and NCUs"
Detailed Description

2.1 Software installation

2.1.1 System requirements

**Hardware requirements**

The following hardware requirements must be fulfilled to allow operation via PG/PC:

- IBM® AT-compatible PG/PC with 486DX33 microprocessor
- At least 8 MB of main memory
- Diskette drive (3 1/2 inch)
- Hard disk drive for data management
- Monochrome or color monitor
- Keyboard
- PG/PC with MPI interface (available for PG 720/720C/740/760)
  Limited operation without MPI card is possible (e.g. interactive programming)
  **Note:** RS232-MPI adapter is not supported.
- Mouse
- Connecting cable for link between PG/PC and NCU module

**Note**

All operator panels and the NCU are either
- connected to the OPI bus or
- connected to the MPI bus.

A **homogeneous** network must be provided with respect to these components.
Software installation

2.1 Software installation

Software requirements

Software configuration for operation via a PG/PC:

- MS-DOS® operating system, version 6.x or higher
- WINDOWS® user interface, version 3.1 or higher
- MPI interface driver (contained in the supplied software)
- WINDOWS® 32s, version 1.30.166.0 or higher
  (You will find the current version in “windows\system\win32s.ini”.)
  If WINDOWS™ 32s is not installed, it can be installed from 2 supplied
  diskettes (call setup.exe).

2.1.2 Installation

Storage area of MPI card

The storage area of the MPI card must be excluded from use by the memory
manager (files: CONFIG.SYS, SYSTEM.INI).

Example of entry in SYSTEM.INI:

[386enh]
EmmExclude=..<card area>
(see HW description of card)

Scope of delivery

System software:

- Approx. 10 diskettes with compressed MMC 102/103 software and
  installation tools
- 2 diskettes WINDOWS 32s subsystem (= Microsoft setup)

Please proceed as follows to install the software:

Call

1. Start SETUP.EXE
   Insert the first installation diskette and use the WINDOWS® file manager to start
   the SETUP.EXE file.
   The installation program requests all further inputs or diskette changes required
   in the user dialog.

2. Enter installation path
   Select the directory plus the installation path (see screenshot) to which you wish
   to copy the Software.
   With “Continue”, you continue the installation, with “Exit Setup” you interrupt
   the installation procedure.
   This also applies to further operations.
3. Select operation with MPI or without MPI

Fig. 2-2  Operation with/without MPI
4. **Select turning or milling**

![Image](Fig. 2-3 Select turning/milling)

**Note**

If you want to change the selection mode later, select the directory “mmc2” and copy “dpturn.exe” (turning) or “dpmill.exe” (milling) into the directory “dp.exe”.

5. **Select drive**
only if several local disk drives are available
Select the drive for the tmp directory (see Fig.)

![Image](Fig. 2-4 Select drive)

If this does not apply, select drive C:\.

**Note**

The contents of the directory “tmp” are deleted on the installation drive with each restart of MMC102.

Following the selection, a status display with the inputs made is shown.
6. Press **Continue** to request the installation diskettes.

---

**Note**

Please observe the requests made on the screen.

The program group “SINUMERIK 840D MMC V3.2” is generated. With successful installation, the following message is displayed: “MMC 102 Installation is complete”

If you want to change the installation path, press **Go back**.

7. **Make settings**

7 a **OPI** interface (1.5 Mbaud), configuration: 1 MMC to 1 NCU (on delivery)

Additional settings are not required.

7 b **MPI** interface (187.5 Kbaud), configuration: 1 MMC to 1 NCU (on delivery)

1. Determination of the NCK/PLC bus address

   - if PLC < SW 3.2, then
     
     NC address = 13
     PLC address = 2

   - if PLC ≥ SW 3.2 and module PLC 314, then
     
     NC address = 13
     PLC address = 2

   - if PLC ≥ SW 3.2 and module PLC 315, then
     
     NC address = 3
     PLC address = 2

2. Entering the addresses in files

   - File “S7CFGPGX.DAT”
     
     In the file “S7CFGPGX.DAT” on the MPI driver directory (<installation path>\MMC2\DRV.ID) the following entries must be adapted to the existing hardware configuration by means of an ASCII editor:
2.1 Software installation

# Interrupt setting
“hwint_vector”: Setting the interrupt for the MPI card. This interrupt may not be used by another card (e.g. network adapter).
Default setting: 10.

# Settings for baud rate
“baud rate”, “tslot” and “tgap”: Settings for the baud rate. These 3 settings must always be activated/deactivated together by removing/inserting the leading “#” (comment).
When the baud rate is changed, the setting “ADDRESS1=\PLC, 10000d01” for 1.5 Mbaud or “ADDRESS1=\PLC, 10000201” for 187.5 Kbaud must also be adapted in file <installation path>\MMC2\MMC.ini, section [840D].
Default setting: 1.5 Mbaud.

- File “netnames.ini”
The following lines in the file must be changed:

`# bus = opi must be replaced by = mpi`
`# nck_address = 13 must be replaced by = 3 (if PLC >= SW3.2)`
`# plc_address = 13 must be replaced by = 2 (if PLC < SW3.2)`

2.1.3 Software supplementary conditions

- Function keys
The function keys may not be actuated in any of the displays until the display has fully built up.

- Monochrome screen
When a monochrome screen is used, the colors used by the MMC must be adapted accordingly. For this purpose, select the color scheme “Monochrome” or “Mono positive” in display “Start-up\MMC\Color setting”.

- Easy parameterization
The display “Start-up\MMC\OPI parameters” can now be called even if there is no link to the NC kernel. This means that the OPI parameters for baud rate and network address can be set easily.

Parallel Step7/AS300 application
Installation in parallel with the Step7/AS300 SW can give rise to problems. It may be necessary to reconfigure the drives and restart the system.
2.1.4 Start program

Program call

The MMC 102/103 software is started on a PG/PC either

- from the program manager through selection of the “SINUMERIK 840D MMC V2.3” program group followed by a double click on the “MMC Startup” symbol or

Fig. 2-6 SINUMERIK 840D MMC program group

- from the file manager by a double click on file REG_CMD.EXE.

Communication

If no communication link can be established to the NCK or 611D, then the message “No communication to NCK” is displayed. If the data exchange is interrupted, e.g. by an NCK reset, then the MMC 102/103 software tries to re-establish the communication link itself.

2.1.5 End program

Deselect program

The following steps must be taken to deselect the MMC 102/103 software:

1. Press function key F10
   A horizontal softkey bar is displayed.
2. Press function key Shift + F9
3. End the program by selecting the softkey Exit.
2.2 Operation via PG/PC

2.2.1 General operation

Operating philosophy

The special function keys of the operator keyboard can be used with the full keyboard. Operator inputs can be made using the mouse or via the keyboard.

Key assignments

The following table shows the assignments between the function keys and the softkeys/special keys:

Note

The editor displays only the characters which can be input via the operator panel keyboard.

Table 2-1 Key assignments between operator keyboard and full keyboard

<table>
<thead>
<tr>

</tbody>
</table>

Alarm or message line

3000 EMERGENCY STOP

Alarm or message line for displaying information for the operator.
### i-R

Selection fields i and R which appear in every display have the following meaning:

- The i field is selected with the **Help key** or by a **mouse click**. No help information is available in Software Version 1.
- The R field is selected with the key **F9** or by a **mouse click**. Selection of this field activates the Recall function, i.e. returns the user to the preceding level.

#### Input fields

<table>
<thead>
<tr>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Traversing range upper limit</td>
<td>0</td>
</tr>
<tr>
<td>Traversing range lower limit</td>
<td>0</td>
</tr>
</tbody>
</table>

To allow the input of data, the input cursor is positioned in the appropriate input field by means of the **TAB** or **SHIFT + TAB** keys or by a **mouse click**. The editing mode is always preset to **Overwrite**. It is possible to switch back and forth between overwrite mode and insert mode by means of the **Insert** key.

#### List fields

<table>
<thead>
<tr>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Measurement Freq. response</td>
<td></td>
</tr>
<tr>
<td>Measured quantity Following error</td>
<td></td>
</tr>
</tbody>
</table>

The functions offered are selected with the cursor keys **UP (↑)** and **DOWN (↓)** or by a **mouse click**. The displayed function is valid.

The list fields are selected by means of the **TAB** or **SHIFT + TAB** keys or a **mouse click**.

#### Single/multiple selector button

<table>
<thead>
<tr>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intern.</td>
<td></td>
</tr>
<tr>
<td>Extern.</td>
<td></td>
</tr>
</tbody>
</table>

The desired function is activated with the cursor keys **LEFT (←)** and **RIGHT (→)** or by a **mouse click**.

The function fields are selected by means of the **TAB** or **SHIFT + TAB** keys or by a **mouse click**.

#### Multiple selector button

- = active
- = not active

#### Single selector button

- = active
- = not active

### Activation of fields

To be able to alter values and functions, the window with the input field must be activated by means of keys **CTRL + TAB** or with the key **HOME** (yellow frame = focus).
2.2.2 Additional information

Axis selection
The "Select axis/Select next axis" inputs in axis-specific displays are always made via the uniformly positioned vertical softkeys AXIS+ and AXIS–.

Function selection/deselection
All functions are activated by means of softkey START and deactivated by means of softkey STOP.

Password
When the softkey Set password is selected, a dialog box is displayed into which the password can be entered. Passwords are input as described in:

References: /BA/, Operator’s Guide
            /FB/, A2, “Various Interface Signals”

Key assignments
Apart from the assignments of keys F1 to F12 and SHIFT + F1 to F10, the conditions and key assignments are the same as those under WINDOWS™ 3.1.

The key combination ALT + TAB can be selected at any time to switch from “Operation via PG/PC” to other WINDOWS™ applications.
2.2.3 Operation of operator panels

The system responds as follows, for example, when two panels are operated in the configuration illustrated below:

1. The inputs from the MMC or OP030 operator panel have the same priority as regards the NCU.
2. The operator panels are mutually independent in terms of data display, i.e. the display selected on one panel is not affected by the display on the other.
3. Spontaneous events such as alarms are displayed on both control units.
4. The protection level with the highest authorization in accordance with the lowest activated protection level number applies to both operator panels.
5. The system does not provide for any further co-ordination between the operator panels.

For further information, please refer to
References: /FB/,B3, Several Operator Panels and NCUs /BA/ Operator’s Guide

2.3 Simulation of part programs

A Windows 32s, version 1.30.166.0 or higher, must be installed in order to operate the part program simulation.

For operating instructions, please refer to
References: /BA/ Operator’s Guide
Notes
Supplementary Conditions

Availability of function

The “Operation via PG/PC” function is available in the basic version with SW 3.1 and higher. With SW 3.1, the number of NCUs which may be connected is limited to one and the number of operator panels to two. One of them must be an OP030.

With SW 3.2 and higher, an operator panel with MMC 100 or MMC 102/103 can also be connected with up to three NCUs.

Data Descriptions (MD, SD)

No special machine data exist for this function.
Signal Descriptions

No signals are required at the NCK-PLC interface for this function.

Example

None

Data Fields, Lists

No signals or machine data are required for this function.

7.1 Alarms

A more detailed description of the alarms which may occur is given in

References: /DA/, Diagnostic Guide

or in the online help.
Notes
# Remote Diagnosis (F3)

1.1 Remote diagnosis for SINUMERIK (SW 4 and higher)

**Scope of delivery and installation**

The remote diagnosis software SW 5 for SINUMERIK is supplied on a CD-ROM. The CD-ROM contains several directories for creating diskettes. The appropriate directories are divided into different types of installation. Beneath these directories, the installations are divided into diskettes. All of the diskettes each in a subdirectory provide a version of remote diagnosis for different operating systems.

- Windows 95/98/NT: Win32\disks 0–4
- Win 3.x: Win16\disks 1–3
- DOS: DOS\disks 1–3

To create one of these diskette sets, the contents of the corresponding directories of a version are copied to a diskette each.

On SINUMERIK 840D MMC 103, SW 4.x and higher, the Win32 variant is installed in all cases.

Insert the first diskette to start the installation.

Enter the following line in Windows service mode (with MMC environment) in the “Start” menu under “Run”:

- DOS: a:\installed
- Windows 3.x: a:\install
- Windows 95/98/NT: a:\setup

From SW 3.1 onwards, the remote diagnosis option is available for the SINUMERIK 840D. With remote diagnosis, the MMC 102/103 on the machine is connected to another PC via modem, ISDN card, via a serial interface, network or via Internet. On the PC the same display appears as on the control. You can operate the MMC 102/103 from the PC.

**Restrictions regarding the scope of delivery**

To limit the scope of the Installation Guide, only one device was described per connection type as an example.

1.1 Remote diagnosis for SINUMERIK (SW 4 and higher)

Remote diagnosis functions

The remote diagnosis comprises the following main functions:

- Remote Control
- File Transfer
- Chat

Remote Control

The service engineer (viewer) can set up a direct remote control link which allows him/her to operate the control system (host) interactively using a keyboard and mouse. The same functionality and screen contents are available on the viewer side as on the control system (host).

File Transfer

Files can be transferred between PC and control system in both directions.

Chat

The Chat function can be used for communication between the two operators on the PC and on the MMC 103. The operators can enter texts simultaneously via an input window and read messages from the partner in an output window.

Host 840D

With remote diagnosis, the MMC 103 is designated “Host 840D”. Software with the same name must be installed on the MMC 103. Once this software is activated, the MMC 103 can be operated from the “Viewer-PC”.

Viewer 840D

The PC connected to the control system is designated as the “Viewer 840D”. The viewer PC can be run under both Windows 95/98 and NT 4.0. The installation routine detects automatically which operating system is installed.

Modem

Minimum requirements are a 9600 baud modem. This Manual describes the 3Com / US Robotics 56K EXT modem.

ISDN

We recommend the external ISDN terminal adapter 3Com / US Robotics Sportster. It is treated in the same way as a modem. For the ISDN card, the ISA card AVM Fritz!Card Classic is recommended. The ISDN card can be used from the new remote diagnosis version V5.1 on the MMC 103.

Network

The remote diagnosis can also be used on the MMC 102/103 via an Ethernet network using the TCP/IP (Windows sockets) protocol. For the network card, Siemens recommends the 3COM Etherlink III Network Card (3C509B-Combo or 3C905B-TX). In addition, an PCI/ISA adapter must be installed on the MMC 102/103. With the MMC 100.2, no network connection is possible.
1.1 Remote diagnosis for SINUMERIK (SW 4 and higher)

**Internet**

With the MMC 103, V4x. and higher, the remote diagnosis can also be run via the Internet. This requires an Internet provider (e.g., T-Online, AOL) providing a PPP dial-in node (analog or ISDN). In addition, either a modem, an ISDN terminal adapter or an ISDN card is required for the connection from the MMC 103 or PC to the dial-in node. On the Viewer’s side, Windows 95/98 or NT must be installed.

**Gateway**

The remote diagnosis can also be operated over a Windows NT 4.0 gateway. This gateway is the link between the service PC and the MMCs that are connected to the customer Ethernet network. The service PC and the gateway are connected via modem or ISDN. The MMCs are connected to the gateway via Ethernet (TCP/IP). Here there are generally two possibilities:

1. From PC viewer –> gateway host and further from gateway viewer –> MMC host

2. With the gateway as RAS directly from the PC viewer –> MMC host

**Keyboard, mouse**

For more user-friendly operation of the remote diagnosis on the control, connect a keyboard and a mouse if required. These items of equipment facilitate text inputs in the chat window. A keyboard and possibly a mouse are needed in all cases for installation and configuration. The operation of the remote diagnosis is possible on control systems with OP3X or OP01x also without a keyboard.
1.2 Remote diagnosis for MMC 100.2 (SW 5.1.40 and higher)

The option “Remote diagnosis under MMC 100.2” differs in some regards from the remote diagnosis of the MMC 102/103. The differences are explained in this section. The description and instructions for remote diagnosis above generally apply to both MMC 102/103 and MMC 100.2. The differences are each described separately.

Scope of delivery and installation

In contrast to the MMC 102/103, the MMC 100.2 has no free hard disk capacity and is based on the DOS operating system. For this reason, the remote diagnosis software for the MMC 100.2 is supplied on a PC Card. This contains the complete software for using the remote diagnosis functions and is plugged into the MMC 100.2. The scope of functions of the software for the MMC 100.2 is limited, compared with the MMC 102/103. The same software is used on the viewer (PC) as on the MMC 102/103 (see Section 1.1 Scope of delivery and installation).

Note

If you use a Windows operating system on the Viewer PC for remote diagnosis on the MMC 100.2, the DOS software must be installed and operated in the DOS-box of Windows. The Windows versions of the remote diagnosis cannot be used here.

Functions

The connection of the MMC 100.2 (host) to the PC (Viewer) is only possible with a modem. The viewer and host cannot be linked by Internet, network or gateway.

The remote diagnosis option for MMC 100.2 offers the following functions:

- Remote control (cf. MMC 102/103)
- File transfer (cf. MMC 102/103)
- Chat, Dialog; in limited form only via part program

Remote control

The service engineer (viewer) can set up a direct remote control link which allows him/her to operate the control MMC 100.2 (host) interactively using a keyboard and mouse. The same functionality and screen contents are available on the viewer side as on the MMC 100.2 (host).

File transfer

Files can be transferred between the PC and MMC 100.2 via the modem link. The files can only be stored on the MMC 100.2 on Ramdisk E: parallel channel. All other drives have read status only.
1.2 Remote diagnosis for MMC 100.2 (SW 5.1.40 and higher)

Chat

The Chat function is not implemented in the MMC 100.2. The users of the viewer and host can communicate only indirectly by means of a part program.

Host 840D/810D

For the purpose of remote diagnosis, the MMC 100.2 is designated “Host 840D/810D”. Software with the same name must be installed on the MMC 100.2. Once this software is activated, the MMC 100.2 can be operated from the “Viewer-PC”.

Viewer 840D/810D

The PC connected to the control system is designated as the “Viewer 840D/810D”. The viewer PC can be run under Windows 3.1/3.11, Windows 95 or NT 4.0. The DOS variant of the remote diagnosis must be installed.

Modem

Basic prerequisite for communication is a modem with at least 9600 baud, connected to the serial port on the PC and MMC 100.2.
1.2 Remote diagnosis for MMC 100.2 (SW 5.1.40 and higher)

Notes
Detailed Description

2.1 General

2.1.1 MMC 102/103

Software
The supplied software can be used to install the remote diagnosis on a SINUMERIK 840D control system and to integrate it into the area switchover. The software is supplied on a CD-ROM that contains a set of diskettes for installing the remote diagnosis.

Documentation
The supplied CD-ROM contains the Remote Diagnosis Documentation in pdf format (Adobe Acrobat) in the SIEMENS directory. The CD-ROM can be read and printed using Adobe Acrobat Reader (recommended: V 4.0).

Help function
A comprehensive help function is available to provide assistance for remote diagnosis operation on the MMC host and viewer PC; it is used as customary under Windows. The CD-ROM also contains further help files, such as readme.wri, support.wri, siemens_d.wri and siemens_e.wri, tipps_d.wri, tipps_e.wri, faq_d.wri.

Keyboard, mouse
The remote diagnosis function can be operated on the viewer PC by means of a mouse and a keyboard. A keyboard and possibly a mouse are needed in all cases for installation on the control system (MMC 103). The remote diagnosis should therefore already be configured at start-up. In the event of service, it is then not necessary to change anything in the configuration for the remote diagnosis. The remote diagnosis function can be activated without keyboard and mouse.

Communication
Viewer ↔ Host
For communication between the operator on the machine and the service staff on the viewer PC, a so-called chat window is provided. Communication can take place only in the form of text inputs. Here we recommend you use a keyboard.

Second phone link
For larger service activities, a voice connection via a second telephone is recommended.

Input from ext. PC (viewer)
All operating actions (softkeys) can be carried out in the same way as the operating actions on the control system (MMC 103). The MCP cannot be operated.
Caution

In order to activate the machine control panel function, the viewer must request the operator to perform the necessary operations via CHAT or a second phone link. The control system operator is responsible for ensuring that the requested measures can be implemented without endangering personnel or the machinery. The operator must refuse to take any measures that are not guaranteed to be safe. The viewer cannot see the state of the machine or its safety equipment.

2.1.2 MMC 100.2

Software

The supplied software must only be installed on the PC. With all Windows operating systems, the installation of the DOS version must be called via "installd". The DOS version installed can be run either in the DOS box of the Windows operating systems or in the DOS mode of Win95/98. The software for the SINUMERIK 810/840 D MMC 100.2 is available on the PC card that can be inserted in the MMC. It need merely be configured to suit the individual system.

Help function

Use the Help in the software supplied for the MMC 102/103 on the viewer PC. Due to the operating system, the Help on the MMC 100.2 host is the DOS Help. You can call Help by pressing function key "F1" or select it in the "Help" menu.

Keyboard, mouse

The remote diagnosis viewer software can be operated using keyboard and mouse. With the MMC 100.2, only the keyboard can be used.
2.2  Hardware configuration for remote diagnosis

2.2.1  Modem, analog or ISDN

The external PC and the MMC are connected to an analog or ISDN modem via a V.24 interface. Both modems can be connected to one another via an analog or ISDN telephone link.

**Hardware configuration**

- **Requirements of MMC (host)**
  - MMC 103
  - Approx. 7 MB free memory on your hard disk (only MMC 103)
  - 1 free COM port:
    - In the MMC 103, it must be made sure that the Com port for the modem is not yet occupied by the V.24 or programming device interface.
    - To this aim, the following operation must be carried out:
      1. Select the area switchover key.
      2. Select “Services”.
      3. Select both “V.24” and “PG” and check the reserved Com port. If the same Com port as the modem is used, then select “none”.

---

**Fig. 2-1** Hardware configuration for remote diagnosis: Modem, analog / ISDN
2.2 Hardware configuration for remote diagnosis

Requirements of PC (VIEWER)

- IBM AT or 100% compatible PC, Intel 486 or higher
- Windows 95/98 or Windows NT 4.0 operating system
- RAM according to operating system requirements
- Approx. 7 MB hard disk storage
- VGA or SVGA screen

Modem requirements

A modem with 14,400 baud or higher and the correspondingly specific driver must be installed and configured before installing the remote diagnosis tool. We recommend using brand name modems such as 3COM / US-Robotics Sportster Flash or Voice 33.6 PnP External for an analog connection and the 3COM / US-Robotics Sportster ISDN terminal adapter for ISDN connections.
2.2.2 Network (MMC 102/103 only)

![Diagram of Hardware configuration for remote diagnosis: Network]

**Hardware configuration**

The external PC has a network card. The MMC 102/103 is equipped with an ISA BOX with a network card fitted (we recommend 3COM Etherlink III, 3C509B-Combo). Both computers are connected via an appropriate Ethernet cable.
2.2.3 Internet (MMC 102/103 only)

Precondition for this solution is an MMC 103 with SW 4.x. In addition, an Internet provider with a PPP (point-to-point protocol) dial-in node is required on both sides. This documentation describes an Internet connection via the German provider T-Online.

**Hardware configuration**

Fig. 2-3 Hardware configuration for remote diagnosis: Internet
2.2.4 Windows with gateway (MMC 102/103 only)

The basis of this solution is a gateway PC which must run under Windows NT 4.0 workstation or server.

There are two possibilities for the remote diagnosis connection via the gateway:

1. From PC viewer -> gateway host and further from gateway viewer -> MMC host (cascading)
2. With the gateway as the RAS server remote diagnosis directly from the PC viewer -> MMC host. In this case, the Gateway PC must be configured as the RAS server.

In the case of the 2nd solution, the licenses for an additional host and viewer are not required, and the performance is a bit better.

Note

Only the first solution is described in this Documentation.
2.3 Software installation and start-up of the communications I/O

2.3.1 Installing and configuring an analog modem

Installation the modem on MMC 103

MMC 103 (host) specific steps:

1. Start the MMC 103 in Windows service mode. (Items 2 to 5 only apply when the MMC 103 is generally restarted. If the computer was shutdown using the menu “Start”, “Exit”, the MMC starts again automatically. Respond to the one prompt displayed by selecting “2” (start Windows; change ini files). Otherwise continue with point 6).

2. Switch the control system on. When the text “Starting Windows 95” appears on the screen, press the key “6”. The control’s service menu is overlaid.

3. Select key “4” from the menu.

⇒ Start Windows (service menu)

You will be prompted to enter a password: “passwd:”

(The password authorizes to perform essential intervention on the control system. It corresponds to one of the following access levels:
– System
– Manufacturer
– Service).

Note

The password must be entered in uppercase letters.

4. Another menu is displayed. Choose key “2”,

⇒ Windows (Changing Environment for MMC2)

5. The Windows operating system is started.

Installing the modem under Win95/98/NT4.0

General steps (viewer/host):

6. Call the installation program:

Double-click on the modem icon to start the installation program via “Start/Settings/Control Panel”.

7. Select type of modem (only Win98):

From the dialog box “Install New Modem”, choose the option “Add”. Click “Next” to continue the installation.

8. Modem Detection:

Choose “Select Modem (Don’t detect my modem; I will select it from a list)” to save time (use the TAB key for selection without using the mouse; press the spacebar to confirm your selection).
9. Setting up a new modem:

Insert the driver diskette supplied with the modem, e.g. “Windows95 Drivers, V2.2, PN:2.018.010-E” and click on “Have Disk...”. Enter “a:" as source in the next input field. Select the driver “U.S. Robotics 56K FAX EXT”. If it is the first time that a modem is installed on your control system, in addition, you will be asked on which COM port you wish to install the modem. Choose a free COM port. If you then click “Next”, the data are copied into the appropriate directory.
10. My locations:

![Location Information Dialog Box]

In this box, enter country code, area code, extension and MVF (tone dialing). Select "Next".

Select "Finish".

A message is displayed stating whether the modem configuration was successful.

**Windows 95 modem settings**

If you wish to modify your modem settings later, there are two possibilities to start the configuration tool for the modem.

1. Boot the MMC in Windows service mode and, as in **Win95/98 and NT4.0**, choose the menu "Start/Programs/Settings/Control Panel"; then double-click on the Modem icon.

2. Activate the appropriate password in the MMC. In MMC mode, configure the modem by choosing the menu "Configure/Options" from "Diagnostics" → "Remote Diagnosis". Then click on the "Configure" button alongside "Modem".
Then you can configure the modem as follows:

![Modem Configuration Dialog Box]

The settings:
- V.24 interface (COM1, COM2, ...)
- Modem volume
- Baud rate (transfer speed)

can be adapted in this dialog box.

**Note**

Make absolutely sure that the modem settings of viewer and host are the same. Otherwise, it is possible that no connection is set up.
The setting “Wait for dial tone before dialing” must be deactivated when using a PABX.

The settings for “Port Settings...” and “Advanced...” must be made as follows:
In the event that problems occur during connection setup, it is advisable to activate the “Record a log file” field. The cause will be logged in the file “c:\win95\modemlog.txt”.

Advanced Port Settings

- Use FIFO buffers (requires 16550 compatible UART)
- Select lower settings to correct connection problems.
- Select higher settings for faster performance.

Receive Buffer: Low (1) High (14)
Transmit Buffer: Low (1) High (16)
2.3.2 Installing and configuring the ISDN terminal adapter

The following description only applies to the 3COM / US-Robotics Sportster TA terminal adapter.

**Installing the ISDN terminal adapter on MMC 103**

MMC 103 (host) specific steps:

1. Start the MMC 103 in Windows service mode. (Items 2 to 5 only apply when the MMC 103 is generally restarted. If the computer was shutdown using the menu “Start”, “Exit”, the MMC starts again automatically. Respond to the one prompt displayed by selecting “2” (Windows; (Changing Environment for MMC2). Otherwise continue with point 6).

2. Switch the control system on. When the text “Starting Windows 95” appears on the screen, press the key “6”. The control's service menu is overlaid.

3. Select key “4” from the menu.
   ⇒ Start Windows (service menu)
   You will be prompted to enter a password: “passwd:”
   (The password authorizes to perform essential intervention on the control system. It corresponds to one of the following access levels:
   – System
   – Manufacturer
   – Service).

4. Another menu is displayed. Choose key “2”.
   ⇒ Windows (Changing Environment for MMC2)

5. The Windows operating system is started.

---

**Note**

The password must be entered in uppercase letters.

---

2/4
General steps (viewer/host):

6. Call the installation program:
   Double-click on the modem icon to start the installation program via
   “Start/Settings/Control Panel”.

7. Select type of modem (only Win98):
   From the dialog box “Install New Modem”, choose the option “Add”. Click
   “Next” to continue the installation.

8. Modem Detection:
   Choose “Select Modem (Don’t detect my modem; I will select it from a list)”
   to save time (use the TAB key for selection without using the mouse; press
   the spacebar to confirm your selection).

9. Setting up a new modem:
   In the left menu select US-Robotics, Inc. Insert the diskette supplied with the
   modem, e.g. “Windows95 Drivers, V2.2, PN:2.018.010-E” and click on
   “Have Disk...”.
   Enter “a:” as source in the next input field.
   Select the driver “Sportster ISDN TA ext. sync. PPP”. If it is the first time that
   a modem is installed on your control system, in addition, you will be asked
   on which COM port you wish to install the modem. Choose a free COM port.
   If you then click “Next”, the data are copied into the appropriate directory.

10. My Location:
    In this box, enter country code, area code, extension and MVF [tone
        dialing]].

11. Select “Finish”.
    A message is displayed stating whether the modem configuration was
        successful.
If you wish to modify the settings of the ISDN terminal adapter later, you can start the configuration tool for the terminal adapter as follows:

Boot the MMC in Windows service mode and, as in Win95/98 and NT4.0 choose the menu “Start/Programs/Settings/Control Panel”; then double-click on the Modem icon.

Then you can configure the modem as follows:

**Windows 95 ISDN modem settings**

![Sportster ISDN TA ext. sync. PPP Properties](image)

The settings:
- V.24 interface (COM1, COM2, ...)
- Baud rate (transfer speed)

can be adapted in this dialog box.

**Note**

Make absolutely sure that the modem settings of viewer and host are the same. Otherwise, it is possible that no connection is set up.
The setting “Wait for dial tone before dialing” must be deactivated when using a PABX.

The settings for “Port Settings...” and “Advanced...” must be made as follows:
In the event that problems occur during connection setup, it is advisable to activate the “Record a log file” field. The cause will be logged in the file “c:\win95\modemlog.txt”.

The same US-Robotics ISDN TA, for example, can be used on the viewer side. In this case, the same must be configured similarly, depending on the viewer version used (Win 3.1X, 95, 98, NT). It is also possible to use the modem entry “AVM ISDN – ISDN (X.75)” under Windows 95/98 on the viewer side in conjunction with the AVM Fritz!Card.

**Note**

On the MMC 103, the Fritz!Card only operates satisfactorily via the CAPI2.0 interface from version 4.3 onwards.
2.3.3 Installing and configuring the ISDN Fritz!Card

The use of the ISDN Fritz!Card (ISA and PCI) is possible on the MMC103 from version 4.3 onwards.

### Installing the ISDN Fritz!Card on the MMC 103, version 4.3 and higher

Before you can start with the installation on the MMC 103, the following steps must be carried out:

**MMC 103 (host) specific steps:**

1. Start the MMC 103 in Windows service mode. (Items 2 to 5 only apply when the MMC 103 is generally restarted. If the computer was shutdown using the menu "Start", "Exit", the MMC starts again automatically. Respond to the one prompt displayed by selecting "2" (Windows; (Changing Environment for MMC2). Otherwise continue with point 6).

2. Switch the control system on. When the text “Starting Windows 95” appears on the screen, press the key “6”. The control’s service menu is overlaid.

3. Select key “4” from the menu.
   ⇒ Start Windows (service menu)
   You will be prompted to enter a password: “passwd:”
   (The password authorizes to perform essential intervention on the control system. It corresponds to one of the following access levels:
   – System
   – Manufacturer
   – Service).

4. Note
   The password must be entered in uppercase letters.

5. Another menu is displayed. Choose key “2”.
   ⇒ Windows (Changing Environment for MMC2)

6. The Windows operating system is started.

### Installing the ISDN Fritz!Card under Win95/98/NT4.0

**General steps (viewer/host):**

6. Carry out the installation:
   For the description of the installation, refer to the documentation of your Fritz! Card, since both the ISA and the PCI ISDN Fritz!Card can be used.
2.3.4 Installing and configuring a network

Installing the Ethernet card 3COM Etherlink III Combo on MMC 102/MMC 103

Exit Windows via the Program Manager (up to V3.x) or, with V4.x and higher, use “Start” (CTRL+ESC) → “Shut Down” → “Shut down the computer?” → “Yes”. The following prompt is displayed:

“Save Windows Environment for next MMC Start [Y,N]?”
Enter “Y” (Yes).
Select “5” (Return to Main Menu).
Select “3” (DOS Shell)
Enter “passwd:”.
An MS-DOS Shell is opened.

Insert the driver diskette supplied with the card into the floppy drive that is connected to a PC/programming device either locally or via Interlink. Enter “a:\INSTALL” if you are using a local floppy disk drive. Enter “e:\INSTALL” if you are using a floppy disk drive connected via Interlink.
Select “Y=Agree to License”.
Select “[ENTER]=Continue”.
Select “Configuration/Diagnostic/Troubleshooting”.
Select “Configuration and Diagnostic Program”.
The adapter is automatically detected. Configure it as follows:
Select “Install” → “Configure Adapter”.

Make the following settings in the dialog boxes:
I/O Base Address: Select “300h”.
The next setting for the IRQ is important as IRQ 10 is already assigned. Interrupt Request Level: Select “11”.
Select Boot PROM: “Disabled”.
Transceiver Type: According to the network connection cable used, e.g.: “On-Board Coax (BNC)” with an RG58 (Cheapernet) network cable.
Do not use “Auto select”, as this can cause problems!
Network Driver Optimization: Select “Windows or OS/2 Client”.
Set Maximum Modem Speed: “9600 baud”.
Plug and Play Capability: “Disabled”.
Full Duplex: “Disabled”.
Activate “OK”.
The configuration is stored in the Etherlink III.
Press “ESC” 3 times to exit the program.

Exit the DOS Shell with “Exit”.
Select “4” (Start Windows (Service Mode)).
Type “passwd:”.
Select “2” (Windows (Changing INI files for MMC2)).
Windows is started. Now you can carry out instructions in the next chapters.

Configuring the Ethernet card with PnP disabled and MMC-BIOS up to V2.12

Insert the driver diskette supplied with the card into the floppy drive that is connected to a PC/programming device either locally or via Interlink.
Enter “a:\INSTALL” if you are using a local floppy disk drive.
Enter “e:\INSTALL” if you are using a floppy disk drive connected via Interlink.
Select “Y=Agree to License”.
Select “[ENTER]=Continue”.
Select “Configuration/Diagnostic/Troubleshooting”.
Select “Configuration and Diagnostic Program”.
The adapter is automatically detected. Configure it as follows:
Select “Install” → “Configure Adapter”.

Make the following settings in the dialog boxes:
I/O Base Address: Select “300h”.
The next setting for the IRQ is important as IRQ 10 is already assigned. Interrupt Request Level: Select “11”.
Select Boot PROM: “Disabled”.
Transceiver Type: According to the network connection cable used, e.g.: “On-Board Coax (BNC)” with an RG58 (Cheapernet) network cable.
Do not use “Auto select”, as this can cause problems!
Network Driver Optimization: Select “Windows or OS/2 Client”.
Set Maximum Modem Speed: “9600 baud”.
Plug and Play Capability: “Disabled”.
Full Duplex: “Disabled”.
Activate “OK”.
The configuration is stored in the Etherlink III.
Press “ESC” 3 times to exit the program.

Exit the DOS Shell with “Exit”.
Select “4” (Start Windows (Service Mode)).
Type “passwd:”.
Select “2” (Windows (Changing INI files for MMC2)).
Windows is started. Now you can carry out instructions in the next chapters.

Configuring the Windows network:
If you encounter problems when configuring the network, please refer to the c:\windows\network.wri file.
Check the Windows start entry in the c:\tools\loadmmc2.bat boot file:

With “C:\WINDOWS\WIN /N: ” delete the option “/N” (network No) if necessary!
Alternatively, you can insert “/N” if no network is connected, without removing the network configuration.
Load the network drivers for Windows for Workgroups up to MMC 102/103, V3.6

From the Main Program Group in the Windows Setup, choose the subitem “Change Network Settings” from the menu “Options”. Click on the “Networks” command button. A new screen form is overlaid. Select “Install Microsoft Windows network” and confirm with “OK”. Click on the “Drivers” command button. A new screen form is overlaid. Activate “Add Network Adapter”. A new screen form is overlaid. Select “Unlisted or Updated Network Adapter” and confirm with “OK”.

Note

If any problems occur with access to the diskette, switch off the MMC 102/103 and then on again and continue the configuration with starting the DOS-Shell using the key “3”.

Insert disk 1/2 labeled ‘3COM EtherDisk for Etherlink III Adapter V4.2 or higher.
Enter “A:\WF\WFW311” and confirm with “OK” if you are using a local floppy disk drive.
Enter “E:\WF\WFW311” and confirm with “OK” if you are using a floppy disk drive connected via Interlink.

Installing the drivers from MMC V6.1

Select “3Com EtherLink III (3C5X9)” and click “OK” to confirm. Select “3Com EtherLink III (3C5X9) [NDIS2/NDIS3]” and confirm with “Setup”. Set Base I/O Port (hex) to “0x0300” and confirm with “OK”. Confirm all menus with “Close” or “OK” until the following prompt is displayed. For “Microsoft Windows Network Names” make, for example, the following entries:

USER name: SIN840D
Workgroup: MyCompany
Computer name: SIN840D

Confirm the message “The files for Enhanced Mode Protocol Manager are currently installed on your Computer” with “Yes to All”.

After the installation you must return to Windows. Do not start Windows again as the settings will be lost if you do!
MMC 103, V4.2 and higher:
Installing the Windows 95 network drivers:
Configure the following via “Start” (CTRL+ESC) → “Settings” → “Control Panel” 
→ “Add New Hardware”:
Select “Next”.
“The question “Do you want Windows to search for new Hardware?” is 
displayed. Reply with “No” and confirm with “Next”.
Select “Network Adapters”.
Insert the diskette labeled ‘3COM EtherDisk for Etherlink III Adapter V5.0 or 
higher’.
Select “Have Disk”. Under “Copy Manufacturer’s files from:” enter “A:" and 
confirm with “OK”.
Select “3Com EtherLink III (3C509/3C509b) in ISA mode” and press “OK” to 
confirm your selection.
Accept the setting selected by Windows 95 with “Next” (the setting is corrected 
later).
Confirm the message “Please insert the disk labeled ’Windows 95 CD-ROM’, 
and then click OK by clicking on “OK”.
A new box is overlaid. Under “Copy files from:” enter “C:\W95INST” and confirm 
with “OK”.
Respond to the prompt “Do you want to keep this file?” with “Yes” for mapi32.dll 
and vredir.vxd.
Select “Finish”.
You are asked “Do you want to shut down your computer now?”. Reply 
“No”.
Shut down Windows via “Start” (CTRL+ESC) → “Shut Down” → “Shut down the 
computer?” → “Yes”.
The following prompt is displayed: “Save Windows Environment for next MMC 
Start [Y,N]?”. Confirm with “Y” (Yes).
Select “2” (Overwrite your last saved Windows Environment with the current 
one).
Select “2” (Windows (Changing Environment for MMC2)).
Wait until Windows 95 is started with active network.
If the box “Enter Network Password” is displayed, enter the following:
User name: e.g.: chris
Password: e.g.: RETURN for no password
Confirm new password: e.g.: RETURN
Correcting the Windows 95 network driver configuration:
Configure the following via “Start” (CTRL+ESC) → “Settings” → “Control Panel” 
→ “Add New”:
Select “3Com EtherLink III (3C509/3C509b) in ISA mode”. Under “Properties” 
click on the “Resources” tab (use the TAB key to change to the relevant tab and 
use the cursor keys to select).
Under “Configuration type:” select “Basic Configuration 0”; under “I/O address 
range” enter “300 – 30F” and confirm both settings with “OK”.
You are asked “Do you want to shut down your computer now?”. Reply 
“No”.

TCP/IP on 
MMC 102

Installing the TCP/IP protocol
For installation, the MS TCP/IP 32 stack is required. For further information 
please refer to the appropriate contact person.
2.3 Software installation and start-up of the communications I/O

Setting up a TCP/IP protocol on MMC 103

1. From the “Start” menu, choose → “Settings” → “Control Panel” → “Network”.
2. Click on “Add” and select “Protocol” in the overlaid dialog box.
3. In the second dialog box, select “Microsoft” in the left selection field and “TCP/IP” in the right one.
4. Confirm with OK to add the new network protocol.
5. Start the PC again to validate the changes.
6. From the “Start” menu, choose → “Settings” → “Control Panel” → “Network”. You can view or edit the IP address by double-clicking on the “Network components” symbol in the display window or by selecting “Properties”. This IP address is required by the viewer for connection setup.
7. Save all current settings, or else they will be lost at restart. Power down the computer via “Shut down” and “Shut down Computer” in the Start menu.
8. The following prompt is displayed: “Save Windows Environment for Next MMC start Y, N?”

Important
Confirm by typing “Y”.

Another question is displayed: “...overwrite them with the current one?”

Respond with “1” (Overwrite...). You can start Windows again or boot the control in MMC mode. (Alternatively continue with point 7).

To be on the safe side, press “2” (Start Windows) again. Shut down Windows again via “Start” and “Shut Down”. Respond to both queries as described above. The backup is saved a second time and the configurations are also saved should an error occur.
2.3.5 Installing and configuring the Internet (for MMC 103, SW 4.2 and higher)

Configuring the long-distance data transmission network for T-Online PPP Internet access

Prerequisite for a remote diagnosis via the Internet is the connection setup via a long-distance data transmission network (long-distance data transmission / Internet). This is set up under Windows 95 on the viewer PC and in Windows service mode on the MMC 103. The following two requirements must be met before the actual Internet access can be configured under Windows 95:

- A modem, ISDN terminal adapter or ISDN card
- Long-distance data transmission network

A new connection is established using the long-distance data transmission network. The installation is completed once this connection has been set up.

Windows 95 can establish long-distance connections (long-distance data transmission) only via a modem. For the installation instructions of the modem, please refer to the supplied Manual or follow the steps mentioned in Section 2.2.1.

Modem, external ISDN terminal adapter or ISDN card

An analog modem is not necessary if an ISDN access and an ISDN card already exist. Since Windows 95 can directly serve only modem connection, a modem must be simulated for the PC. In general, appropriate drivers are either supplied with the ISDN card or can be obtained from the manufacturer.

The company AVM supplies a driver that works with many ISDN cards. This CAPIPORT driver is available for their Fritz!Card. It can also be used with TELES 16.0 and TELES 16.3 PnP. The German Telekom’s Teledat 150, which is also from AVM, operates with the AVM CAPIPORT driver.

Long-distance data transmission network

Install the Windows 95 long-distance data transmission network. To do this, start the MMC 103 in Windows service mode with MMC 102 environment. Then proceed as follows:

- Activate “Control Panel” via “Start” and “Settings”.
- Select the option “Add/Remove Programs” and click on “Windows Setup”.
- Select “Communications” by double-clicking on it.
• Select "Communications" by double-clicking on it.
• Activate "Dial-Up Networking" and confirm with "OK".
• The long-distance data transmission network is installed and can be opened by double-clicking on it under My Computer.

The TCP/IP protocol is not automatically added when the long-distance data transmission network is first installed. Do this now via "Control Panel" → "Network" → "Add" → "Protocol" → "Manufacturer Microsoft" → "TCP/IP".
New Connection

Click the icon “Create new Icon” and make a new connection via “Start” (Ctrl + Esc) → “Programs” → “Accessories” → “Dial-Up Networking”:

Select a name for the new connection and select a modem.
Enter the area code without leading zero, the country code for Germany and 191011 as telephone number for T-Online PPP (also without leading zero).

The area code is only of importance should the local access node fail temporarily. You can also change the configuration later (after setting up the connection) to select a cheaper tariff.

Click on “Next” and in the overlaid box on “Finish”. The new connection is stored, but must still be configured before use.

In the “Dial-Up Networking” folder (which is probably still open), right mouse-click on the newly created connection to open the object menu. Select “Properties” and make the following changes to the initial parameter settings.
• Deactivate “Use country code and area code”, as now the number 091011 should be available for T-Online in all areas in Germany. The call number must have a leading zero, or two leading zeros if required, if you are using a PABX.
• Change the modem settings by activating “Configure...”.
• Make the following settings under “Server Type...”:
2.3 Software installation and start-up of the communications I/O

- Type of dial-up server: “PPP: Windows 95”
- Advanced options:
  - Log on to network: OFF
  - Enable software compression: ON
  - Request encrypted password: OFF
- Allowed network protocols: “TCP/IP”

Caution
Only activate “Log on to network” if you are working in a local network. All standalone users (without SINCOM or SINDNC) are much faster if “Log on to network” is deactivated.
• Do not set the IP address. T-Online operates with dynamically allocated IP addresses that are assigned by the server.
• Do not enter the name server address. It is determined by the server at connection setup.
• Activate "Use IP header compression" and
• "Use default gateway on remote network".

Close any open dialog boxes with “OK”.

---

Remote Diagnosis (F3)

2.3 Software installation and start-up of the communications I/O
12.95

2.3 Software installation and start-up of the communications I/O

Configuring access to T-Online

Except the access data to T-Online, the newly created connection is now configured. The access data is composed of different numbers that are contained on the order confirmation for your T-Online access. Enter the required data when you establish the first connection with T-Online.

The user name consists of several numbers:

- Twelve-digit connection ID (in this case 000460004256)
- T-Online No. (here: 0733169386). If the number is shorter than 12 digits, it must be followed by "#".
- Number for other user (here: 0001)

Password

Enter the personal password of your T-Online connection, which is to be found on the order confirmation.

You can activate "Save password" to save the encrypted password in a system file. This way it is not necessary to enter the password for every connection setup.

Call number

The call number can be modified here once more if the number 0191011 is not accepted.

Click on "Connect" to set up a connection between the MMC 103 and T-Online.

Small status menus are displayed containing a log of what is currently happening. Lastly the following dialog box is overlaid:

The connection has been set up successfully. The remote diagnosis software can be operated over the Internet.
2.3 Software installation and start-up of the communications I/O

Integration into the MMC user interface

Integration of the Internet dialing via the long-distance data transmission network using the example of a T-Online PPP access. The following files must be loaded:

\texttt{c:\add\_on\regie.ini}

\begin{verbatim}
[TaskConfiguration]
\end{verbatim}

\texttt{c:\add\_on\language\re\_gr.ini}

\begin{verbatim}
[HSsoftkeyTexts]
HSK11 = "Internet Connection"
\end{verbatim}

\texttt{c:\add\_on\language\re\_uk.ini}

\begin{verbatim}
[HSsoftkeyTexts]
HSK11 = "Internet Connection"
\end{verbatim}

\texttt{c:\ Reachout\internet.bat}

\begin{verbatim}
@echo off
rem Set up dial-up connection to T-Online via PPP
rem rundll mauli.dll,RnaDial T-Online per PPP
rem Wait until connection established
rem echo
echo Press RETURN (INPUT) once connection setup
echo successful. If required, switch to the MS-DOS window first
echo via ALT + TAB.
pause
echo
determine your dynamically assigned IP address
echo This address is needed on the viewer side for connection
echo setup.
netstat –r
echo
echo Please pass the IP address displayed in the first line
echo e.g.: 193.159.44.76 on to your colleague on the viewer side.
echo It is needed there for connection setup.
echo Once this is done, press RETURN (INPUT). If required, switch
echo to the MS-DOS window first via ALT + TAB.
echo
pause
rem Start the remote diagnosis
rem c:\Reachout\Hostmenu.exe
\end{verbatim}

If softkey 11 (2nd softkey level of MMC user interface) is not suitable, you can change it in the above files (regie.ini, re\_gr.ini, re\_uk.ini). For the file c:\Reachout\internet.bat, it is necessary to select “Close” in Windows service mode via “Properties” – “Program” when terminating.
2.3 Software installation and start-up of the communications I/O

Configuring the host

In the file internet.bat, the entry “rundll rnaui.dll,RnaDial T-Online per PPP” must possibly adapted to the configured long-distance data transmission connection. Example: The dial-up connection has been named “T-Online per PPP”. Start the configuration as follows: “Start-up” → “MMC” → “Options” → “Remote diagnosis”.

On the MMC 103, start the remote diagnosis configuration menu and select “Internet” as the connection type. Start the remote diagnosis as usual.
Establish Internet connection

Use softkey 11 “Internet Connection” to establish a connection to the Internet and start remote diagnosis via “Diagnosis” → “Remote Diagnosis”. Select “Connect to” to set up the modem/ISDN connection to the Internet PPP dial-up node. The following window is displayed:

After the T-Online PPP connection has been set up, the local dynamically assigned IP address is determined. With the MMC you can change to the window displayed below entering “Alt” and “Tab” on the full keyboard.
Follow the instructions in the MS-DOS window. Pass the dynamically assigned IP address on to your colleague on the viewer side. The IP address is the last group of digits in the first line (here: 193.159.45.207). With the IP address, your colleagues in the service center can set up access to the control over the viewer.

Starting

Starting the host remote diagnosis on MMC103
Start the host via "Diagnosis" → "Remote Diagnosis".

Operation on the viewer side

Establish the Internet connection via the entry configured in the long-distance data transmission network. Start the appropriate viewer and connection setup to the host.

Select "Internet" as connection type in the configuration. Enter the above IP address (e.g. 193.159.45.207) at connection setup in the field "Network Name".
2.3.6 Installing and configuring Windows with gateway (only MMC 102/103)

There are only two possibilities of remote diagnosis connection via the Gateway:

1. From PC viewer → gateway host and further from gateway viewer → MMC host (cascading). The installation and configuration is similar to the installation of the individual components (viewer → host) of the cascade.

2. With gateway as the RAS server, remote diagnosis directly from PC viewer → MMC host. In this case, the gateway PC must be configured as the RAS server.

In the case of the 2nd solution, the licenses for an additional host and viewer are not required, and the performance is a bit better.

Note

Only the first solution is described in this Documentation.
2.4 Software installation and start-up on the 840D with MMC 103, V4.x and higher

Installing remote diagnosis on MMC 103

The installation of the remote diagnosis must be carried out both on a PC (viewer) and on the control system (host). Before the remote diagnosis is installed, the communication devices (such as modem, network card...) should be installed (see Section 2.3).

For the option “Remote Diagnosis”, the software package “Host 840D Remote Diagnosis” is offered. The companion installation program is used to install the remote diagnosis software on the control system (MM103). During the installation, it is imperative to configure an initial user with administrator rights and an appropriate password. If password protection was enabled on the host, a login should be set up on the host for the user on the viewer side, since this is required for establishing the connection on the viewer PC during the remote diagnosis session.

Note

To start up the remote diagnosis, an MFII keyboard must be connected to the MMC 103.

Delivery form

The remote diagnosis is supplied on a CD-ROM. The CD-ROM contains one folder each with installation disks for the operating systems DOS, Win3.11, Win95/98, NT4.0.

Table 2-1 List of CD-ROM folders for the individual operating systems

<table>
<thead>
<tr>
<th>Folder</th>
<th>Operating system</th>
</tr>
</thead>
<tbody>
<tr>
<td>‘DOS’</td>
<td>DOS</td>
</tr>
<tr>
<td>‘Win16’</td>
<td>Win3.11</td>
</tr>
<tr>
<td>‘Win32’</td>
<td>Win95/98, NT4.0</td>
</tr>
</tbody>
</table>

The disks 0 to 4 in the folder ‘Win32’ contain the host for the control system and Win32 Viewer. If the control system has no CD-ROM drive, but, instead of that, a floppy disk drive, the individual directories ‘Disk 0, 1, 2, 3, 4’ must be copied to 3.5” diskettes prior to the installation from the CD-ROM. If the control system also has no floppy disk drive, the installation can also be carried out via Interlink or via a network.

Note

The CD-ROM contains the host for 840D MMC 102/103 and the host/viewer for Windows 3.1/3.11, Win95/98 and NT4.0 (see also Brief Description).
2.4.1 Installing and configuring remote diagnosis from a CD-ROM drive on a PC/PG via the network

If the MMC 102/103 is already connected to a network, the installation is also possible from the CD-ROM drive of a PC/PG (programming device) of the same network. To do so, the corresponding drive of the PC/PG must be enabled in Windows Service Mode and mapped via the control system's Explorer.

**Sequence on the PC/PG**

1. Start the Explorer, click with the left mouse button on the CD-ROM drive and choose “Sharing...” from the menu displayed.

**Note**

If you cannot find the menu entry “Sharing...”, select the setting “File” and “Print Sharing...” via “Start” → “Settings” → “Control Panel” → “Network”. In the new dialog box, select the first item “I want to able to give others access to my files.”; then click OK to close all open boxes.

![CD-ROM Properties](image-url)
2. Settings in the Properties box of the CD-ROM drive:
   A. Select “Shared As”.
   B. Assign a name for the drive.
   C. Assign an access authorization.
   D. If desired assign a password and confirm the box with “OK”.

3. Settings in the Properties box of the CD-ROM drive:

Sequence on the MMC 102/103:

1. Boot the control system in Windows Service Mode.
2. Start the Explorer and select the computer with the CD-ROM drive in the network environment.
3. Click with the left mouse button on the drive with the name “CD-ROM” and choose “Map Network drive...”) from the menu displayed.
4. Click “OK” to confirm the new dialog box.

Note
Make sure that the setting “Reconnect at logon” is not active. Otherwise, the drive will be connected with each logon.

The remote diagnosis software can now be installed using the newly created drive as described in Section 2.4.3.
2.4.2 Installing and configuring remote diagnosis from a floppy disk drive on a PC/PG via V.24

Sequence

Connect a notebook or programming device (PG) to the X6 interface (COM1) via a zero-modem cable.
Boot the notebook in DOS mode and start the InterServer program (Intersvr.exe).
Switch on the control.
The floppy disk drive will now be detected by the control system as a drive and can be addressed by the control system, e.g. under e:\.
To complete the installation, proceed as with installation via a separate drive (see Section 2.4.3).
2.4.3 Installing and configuring remote diagnosis from a floppy disk drive directly on the control system with MMC 103, V4.x and higher

Sequence

Connect MFII keyboard!

1. Switch the control system on. When the text “Starting Windows 95” appears on the screen, press the key “6”. The control’s service menu is overlaid.

2. Select key “4” from the menu.
   ⇒ Start Windows (Service menu)
   You are prompted for your password.
   “passwd:”
   (The password authorizes you to make significant changes in the control. It corresponds to one of the following access levels:
   – System
   – Manufacturer
   – Service).

Note

The password must be entered in uppercase letters.

3. Another menu is displayed. Now select key “2”.
   ⇒ Start Windows (Changing INI-Files for MMC2)

4. The Windows operating system is started.
   Insert the first diskette (remote diagnosis for WIN32 + DOS Disk0) into the floppy disk drive.
   With V4.x and higher, call the “Start” program menu by pressing “Ctrl” and “Esc” and use the cursor keys to select “Run”.
   Type a:\setup32 at the prompt, if your floppy disk drive is drive “a”. Otherwise type the appropriate letter for the drive. (“z” with Interlink). Press “Return” to continue.

5. Installing the remote diagnosis software:
   If Winsock2 is not yet installed on the control system, Winsock2 will be installed prior to the remote diagnosis installation.

The following box is displayed:
Confirm the next box with “OK”.

The installation is continued.

**Note**

It may possibly take 20 seconds until the next window appears.

5.a) Welcome dialog: Type ‘Next’ to continue with setup.

**Note**

Use the TAB key to change between the different selection fields and press Return to confirm. Select a menu by means of keyboard input of “Alt” and the letter that is underlined in the menu name.
5.b) License Agreement: Read it carefully and click "Yes" to confirm.

5.c) User information and serial number:

You will be asked to enter end user information and serial number.

Type the serial number supplied with the remote diagnosis software and choose "Next".
5.d) Path specification:
Choose "Next" to continue with setup without changing the default directory "C:\ReachOut".

5.e) Select type of installation:
Select "Typical" for a standard installation.
5.f) Choose a program group:
Select a program group where you wish the program icons to be stored and then click 'Next'.

5.g) Enter your personal data:
This dialog box will only appear if the remote diagnosis is reinstalled or installed for the first time.
Enter your personal data and the serial number of the remote diagnosis and click 'Next' to confirm.
5.h) Verify the setup information:
   If the information is correct, click 'Next' to continue with the setup;
   otherwise, click 'Back' and correct the information.

5.i) Copy the data onto the MMC:
   The remote diagnosis directory is created, and the files are copied.

After the first diskette (Disk0), the setup program will ask you to insert the
Disk#1.
2.4 Software installation and start-up on the 840D with MMC 103, V4.x and higher

5.j) End of installation:
At the end of installation, first the “ReachOut” window with all program icons is opened.

The you will be asked whether you wish to restart Windows immediately.
If no TCP/IP has been installed on the MMC, an information is displayed after installation of the remote diagnosis software that remote diagnosis requires WinSock2 Patch for the TCP/IP functionality in case a network connection is to be added to the computer at a later date. The window must be confirmed with “OK”. Otherwise, there are no other consequences regarding the functionality of the remote diagnosis. Immediately afterwards, the computer asks you if you want to restart Windows immediately.

**Note**

From the dialog box “Restart”, choose the option “No, I will restart my computer later” and quit the box with “Finish”. Confirm the next following message box “Information” with “OK”, shut down the MMC103 V4.x using the start menu “Shut down” and by selecting the option “Shut down Computer” in the next following box. Confirm the two next following queries with “Y”.

Before you can use the remote diagnosis, you must configure it according to the description in Section 2.4.3.
A connection between viewer and host can only be established if the host is made ready to receive after starting the remote diagnosis on the MMC and then selecting and correctly configuring the appropriate communication devices.

To this aim, proceed as follows:

**Sequence**

1. Switch the control system on. When the text “Starting Windows 95” appears on the screen, press the key “6”. The control’s service menu is overlaid.

2. Select key “4” from the menu.
   
   "passwd:"
   
   (The password authorizes you to make significant changes in the control. It corresponds to one of the following access levels:
   
   – System
   – Manufacturer
   – Service).

3. Another menu is displayed. Now select key “2”.

4. The Windows operating system is started.

5. If the remote diagnosis was not started automatically, start it by clicking on the following icon:

6. Select the menu option “Configure/Options...”.

---

**Note**

The password must be entered in uppercase letters.
7. Make the host ready to receive:
Select the option “Wait for Calls”.

8. Choose a communication device:
Select the used communication device and, if necessary, choose “Configure” to adapt the device settings.

**Note**

In the “Options” dialog box, only devices can be selected, which have already been installed on the MMC. For this reason, first install and configure the communication devices to be used (see Section 2.2) and the install and configure the remote diagnosis.

9. Time when the host is ready to receive:
For “Start waiting for calls”, choose the option “When ReachOut starts” to make sure that the host is ready to receive after starting the remote diagnosis.
2.4.5 Uninstalling the remote diagnosis software on MMC 103, V4.x and higher

Use “Changing Environment for MMC2” to change to Windows Service Mode.
Start the Uninstall procedure via “Start” (Ctrl + Esc) -> “Programs” ->
“ReachOut” -> “Uninstall” -> “Yes”. The question “… Delete all remaining
files …” may be displayed. Respond with “Yes”.
Shut down Windows service mode via “Start” (Ctrl + Esc) -> “Shut Down” ->
“Shut down the Computer?” -> “Yes”.
Save the environment with:
“Save Windows Environment for …” -> “Yes” -> “1.” ->
“2” Windows (changing...)
Save the environment again with:
“Start” (Ctrl + Esc) -> “Shut Down” -> “Shut down the computer?” -> “Yes” ->
“Save Windows Environment for …” -> “Yes” -> “1” ->
“2” Windows (changing...)

All remote diagnosis files and all entries in the SYSTEM.INI file are removed.
2.5 Software installation and start-up on the 840D with MMC 102/103 V3.x

2.5.1 Installing and configuring remote diagnosis (Win16 version) from a floppy disk drive directly on the control system with MMC 103/103, V3x

Sequence

1. Connect MFII keyboard!
2. Switch the control system on. Press key “6” when the text “Starting Windows 95” (or with Software Version 3.x “Starting MS-DOS”) is displayed on the screen. The control’s service menu is overlaid.
3. Select key “4” from the menu.
   ⇒ Start Windows (Service menu)
   You are prompted for your password.
   “passwd:”
   (The password authorizes you to make significant changes in the control. It corresponds to one of the following access levels:
   – System
   – Manufacturer
   – Service).
4. Another menu is displayed. Now select key “2”.
   ⇒ Start Windows (change ini Files)
5. The Windows operating system is started.

   Insert the first diskette (remote diagnosis for WIN + DOS Disk 12) into the floppy disk drive.
   With V4.x call the “Start” program menu by pressing “Ctrl” and “Esc” and use the cursor keys to select “Run”.
   With V3.x call the “File” program menu by pressing “ALT” and “F” and use the cursor keys to select “Run”.
   Type a:\install at the prompt, if your floppy disk drive is drive “a”. Otherwise type the appropriate letter for the drive. Press “Return” to continue.

5. Installing the remote diagnosis software:

Note

The password must be entered in uppercase letters.

Note

Use the TAB key to change between the different selection fields and press Return to confirm. Select a menu by means of keyboard input of “Alt” and the letter that is underlined in the menu name.
5.a) User information, type of installation and path

This display prompts you for end user information and serial number input.

Enter the serial number supplied with the remote diagnosis software and select “Continue”.

Confirm with “Yes”.
Enter the directory the software is to be installed in. The standard setting is the c:\reachout directory, this is the only directory that the installation software copies and handles data in. This directory must NOT be changed! Select “Custom”.
5.b) Selecting the software components to be installed.

On the SINUMERIK 840D MMC 102/103, select the Windows and DOS host only. Deactivate the “Modem Pool” component.
5.c) Copying data to the MMC

When the settings are made in the “Custom” display, the remote diagnosis directory is created on the MMC and the files are copied.

The setup program prompts you to insert #2 Disk.

Insert #2 Disk into the drive, type "disk2" instead of "disk1" and click on "Continue". Repeat this procedure for #3 Disks.

Wait until all files have been copied.
5.d) Configuring the type of connection

Select the connection type you expect to use first. You can add other selections after you install ReachOut.

**Connection Type**

- Modem
- Network
- Modem Pool/ACS
- Direct Connect Cable
- Internet
- Remote Node
- ISDN
- Cellular Modem

Select the connection type. The default setting is “Modem”. If the connection is to be set up via ISDN, a network or the Internet, please go to the appropriate page in this documentation.

5.e) Host identification name

Enter a unique name that ReachOut will use to identify this computer.

**MMC 103–1**

Allocate an unambiguous identification name for the remote diagnosis. The name is displayed on the PC (viewer) at connection setup. If several MMC 102/103’s are installed at a customer’s, it is advisable to use unambiguous names (e.g. stocktaking number, machine number etc.).
5.f) Communications port

Check the checkbox with the number of the interface your modem is connected to. On the MMC 102/103 COM1 corresponds to connector X6, COM2 corresponds to connector X7.

5.g) Modem type

Select the modem that is connected. If it is not listed, select a similar one or the “Hayes AT compatible” modem driver. The modem configuration can be changed or expanded at any time later.
5.h) Automatic start

You are prompted whether the remote diagnosis is to be included in the Windows autostart group. Reply that you don’t want this to happen. The remote diagnosis must be activated separately via menu commands specifically set up for this purpose. You can read in the Tips_x.wri file how to start the remote diagnosis automatically.

5.i) Password and user

A user and password can be configured at installation. The operator on the viewer side has to know this password as it is required for the remote diagnosis session on the viewer PC after connection setup.

Confirm with “OK”.
12.95

2. Software installation and start-up on the 840D with MMC 102/103 V3.x

Under “Callback” you can make optional settings, e.g. if you want to configure a callback number for security reasons. (See Tips_x.wri file.)

5.j) End of installation

Note
At the end of the installation procedure for remote diagnosis, the system asks you whether you want to restart Windows. Select “Return to Windows” and shutdown the MMC 103 with V4.x via the start menu “Shut down” and “Shut down computer”, or on the MMC 102 with V3.6 via “File” in the Program Manager.

6. After Windows has been shutdown, the following prompt is displayed: “Save Windows Environment for Next MMC start [Y, N]?”
Important
Respond to the prompt “Save Windows Environment for Next MMC start [Y, N]?” by pressing “Y”.

Another question is displayed:
“...overwrite them with the current one ?”
Respond with “1” (Overwrite...). You can start Windows again or boot the control in MMC mode. (Alternatively continue with point 7.)
To be on the safe side, press “2” (Start Windows) again.
Shut down Windows again via “Start” and “Shut Down”. Respond to both queries as described above. The backup is saved a second time and the configurations are also saved should an error occur.

7. Switch off the control.
8. Start the control.
9. Should an error message (the COM port used by the remote diagnosis is already assigned) appear when starting the remote diagnosis, please proceed as follows:
   Start the Services area application.
   First activate the “Interface” softkey, then the vertical softkey “V.24”.
   Change the option “Interface: COM1” into “Interface: none”.
   You can use the interface COM1 (on the control X6).
   Activate the vertical softkey “Programming unit”.
   Change the option “Interface:COM2” into “Interface: none”.
   You can use the interface COM2 (on the control X7).
   The changes are immediately effective unless a V.24 job is being processed; in that case they are valid after the V.24 job is completed.
   Enable the interface used by the remote diagnosis. If necessary, you may have to undo the procedure.
10. The installation procedure for remote diagnosis is successfully completed.
2.5.2 Uninstalling the remote diagnosis software on MMC 102/103

MMC 102/103 with V3.x

Use “Changing Environment for MMC2” to change to Windows Service Mode.

Start the Uninstall procedure via “ReachOut” → “Uninstall” → “Yes” in the Program Manager and respond to “Restart Windows now?” with “No”.

Exit Windows Service Mode in the Program Manager via “File” → “Exit Windows” → “Yes”.

Save the modified INI files with:
“Save INI-Files for...” → “Y” → “2” → “5” Return to Main Menue

Remove the remaining files (only required with remote diagnosis V3.X) as follows:

“3” DOS Shell
“cd windows”
“del_rch.bat”
The message “Batch File missing” can be ignored.
2.6 Start-up and software installation on the MMC 100.2

The MMC 100.2 has no free memory medium on which the software could be installed. For this reason, the "ReachOut" software is supplied pre-installed on a PC card. This card need only be plugged into the MMC 100.2 and configured. The installation routine includes setting the modem and configuring the user with the relevant password.

Note
When installing the remote diagnosis software, an MFII keyboard can be connected to the MMC 100.2. to facilitate data entry.

2.6.1 Installing the PC card on the MMC 100.2

The ports for the interfaces are located on the rear panel of the MMC 100.2. To install the remote diagnosis software, two serial V.24 interface ports (COM 1 and COM 2) are required, one for the modem and the other to connect the PC card.

The slot for the PC card is activated prior to start-up. A row of coding switches are located above the slot for the PC card.

1. Set microswitch 0 to position 1. All other switches must be set to 0.
2. Insert the PC card with the openings upwards into the intended slot.
3. Connect the cable between the modem and MMC 100.2 to one of the two serial ports on the MMC (COM 1 or COM 2).
2.6.2 Installing and configuring the software

The software “ReachOut” required to operate the remote diagnosis is completely installed on the PC card. It need only be configured to match the user’s system before the software is used for the first time.

Call configuration mode

The PC card is installed in the MMC 100.2 and the modem connected. Please proceed as follows to configure the card:

1. Switch the control system on.
2. Press key “6” as soon as the Copyright line containing the serial number is displayed on the screen. The configuration menu appears.

This menu offers you a selection of different actions and you can select the function of your choice with keys “1” to “4”.

<table>
<thead>
<tr>
<th>Key</th>
<th>Description of configuration menu</th>
</tr>
</thead>
<tbody>
<tr>
<td>ReachOut teleservice is enabled at Power On</td>
<td></td>
</tr>
<tr>
<td>1:</td>
<td>Update PC–IN (internal EPROM, COM 1)</td>
</tr>
<tr>
<td>2:</td>
<td>Update PC–IN (internal EPROM, COM 2)</td>
</tr>
<tr>
<td>3:</td>
<td>ReachOut Setup</td>
</tr>
<tr>
<td>4:</td>
<td>Disable Reachout at Power On</td>
</tr>
</tbody>
</table>

Remote diagnosis will not be started with next Power ON

3. Press key “3” to go to the menu for configuring the PC card.

Note

The first line prior to the configuration menus contains the information whether remote diagnosis is enabled or not. If, for example, the line “ReachOut is enabled at Power On” is displayed before the menu, the remote diagnosis is enabled with each Power ON (key “4”). In this case, the configuration menus only offer “Disable ReachOut at Power On” (key “5”) to disable the remote diagnosis with the next start.
2.6 Start-up and software installation on the MMC 100.2

**Setup ReachOut**
Configure the existing hardware in the ReachOut setup menu and define your settings for operation. For initial start-up of the remote diagnosis, you must enter the following settings:

- Select the COM port of the modem
- Set the modem type
- Select the modem transfer rate
- Select the phone line type
- Enter the PCs for connections
- Define the password and access rights
- Enter a telephone number for the Call Back function
- Reboot the system

**Selecting menu items**
The ReachOut menus for the MMC 100.2 are selected with the arrow keys on the operator panel. Each selection is displayed on a yellow background. The selected item can be activated by pressing the Enter key.

**Note**
If you have not connected an MMII keyboard to the MMC 100.2, you can quit the menus using the keys “X” (Exit) or “Cancel”. On the operator panel, the “Esc” key is the “Cancel” key. The function keys “F1” to “F8” are activated via the horizontal keys.

**Help**
The main “Help” menu contains a brief description of each menu. You can also display direct help for any subject by pressing function key “F1”. Use the arrow keys to page through the help topics.

**Select the COM port**
The MMC 100.2 has two COM ports. Check first which of the two ports the modem is connected to. You can set the appropriate COM port in the menu “Comm Port”.

1. Select “Preferences” –> “Communication Settings” in the ReachOut menu bar. A new form with a new menu is opened in which you can enter the “Communication Settings”.
2. In this new window, select “Comm Settings” –> “Comm Port” to display a selection list.
3. Select either serial interface COM 1 or COM 2 depending on the modem connection.
4. Confirm your selection with the Enter key. The menu is closed.
2.6 Start-up and software installation on the MMC 100.2

Note
Both the configuration for **modem type**, **data transfer rate** and **connection type** and for Comm Port is carried out in the screen form “Communication Settings”.

**Modem type**
ReachOut offers a selection list of typical modems to choose from in the screen form for the Communication Settings in the menu “Modem Select”.

2. Select the connected modem and appropriate transfer rate in the “Modem Table”.

Note
If the modem you are using is not contained in the selection list, select “A Hayes Compatible” modem with the data transfer rate of the modem you are using. If you have selected the modem type, the software expects that a modem is installed and turned on.

3. Confirm your selection with the Enter key. The menu is closed.

**Data transfer rate**
ReachOut automatically sets the highest possible transfer rate for the selected modem. You can change the current transfer rate in the “Data Speed” menu in the “Communications Settings” form.

1. Select “Comm Settings” → “Data Speed”. A selection list of transfer rates is displayed.
2. Use the arrow keys to select a transfer rate.
3. Confirm your selection by pressing the Enter key. The menu is closed.

Note
When modems from different manufacturers are used, the same data transfer rate must be set for both viewer and host; otherwise, possibly no connection can be established.

**Phone line type**
Set the modem to tone or pulse dialing in the “Dialing Prefix” menu in the Communication Settings screenform.

1. Select menu items “Comm Settings” → “Dialing Prefix” to call the “Enter Phone Dialog Prefix” menu.
2. Enter the prefix for the desired dialing signal type in the text line.
   - **ATDT**: Tone dialing
   - **ATDP**: Pulse dialing
Note
If you use the Call Back option on private branch exchanges, the string for tone dialing must be **ATX3DT**, with pulse dialing **ATX3DP** to ensure that the dialing tone is ignored. For more detailed information on the prefix **ATXn**, please refer to your Modem Manual.

You can enter additional parameters for PBX systems. Descriptions of these can be found directly in the “Enter Phone Dialog Prefix” menu.

3. Confirm your selection with the Enter key. The menu is closed.
4. Press the **“Cancel”** or **“Esc”** key to exit the Communication Settings screenform. The “Save Current Settings” option window is displayed.
5. Press key **“Y”** to save your settings and return to the main screenform of ReachOut.

Making a connection to a PC

In the menu “Phone Book”, select the PCs with which you want to establish connections.

2. Press key **“A”** (Add New Entry) to enter a new phone connection.
3. Enter a “Description” and “Phone Number”. You can also fill in the “User Name” and “Password” fields if you wish.
4. Confirm you inputs by pressing the Enter key.
5. Repeat the operation if you wish to enter further phone connections.
6. Press key **“X”** (Exit) to close the menu.

Note
Use the “**E**” key (Edit Entry) to modify existing entries. Use the “**D**” key (Delete Entry) to delete existing entries.
### Password and Call Back

Use the “Edit Passwords” menu to define which access rights the user of the viewer PC will have when contacting the host. Each user can also be assigned his/her own password. Only users entered in the list can activate the remote diagnosis function.

1. Select “Security” → “Edit Passwords” in the ReachOut menu bar. The screenform headed “Password List for this computer when it is a host” is then displayed.

2. Press key “A” (Add Password) to record a new user with password. The “Add New Password” screenform is opened.

3. Enter the name and password in text lines “User Name” and “Password”. Select menu item “File Access” to display a selection list in which you can assign varying levels of access rights to the user.

4. If you wish to grant full access rights to the user, select “Full Access” in the list. Select the appropriate entry for restricted rights.

### Call Back

For the Call Back mode, you can enter the phone numbers of the viewer PC. If the host dialed from the viewer PC, no direct connection is established with active Call Back. The host will call back the logged-on viewer PC only with the stored phone number. The remote diagnosis system is not activated until a connection has been successfully set up with Call Back.

Call Back ensures that computers without access authorization cannot perform remote diagnosis. Only viewer PCs and users entered in the host with their phone numbers will be accepted after successful Call Back.

5. Type the phone number of the viewer PC when working with Call Back.

6. Confirm your entries by pressing the “Enter” key and return to the main screenform of ReachOut.

### Defining options for log-on

The logging on process for authorized users can be configured in the “Password Options” menu. You can, for example, define whether passwords are needed or set the maximum number of log-on attempts.

1. Select “Security” → “Password Options” in the ReachOut menu bar. The “Password Options Menu” screenform is opened.

2. You can activate or deactivate the relevant configuration by pressing keys “1” to “4”.

3. Press the “Cancel” or “Esc” key to go to the ReachOut main screenform.

---

**Caution**

The other setting options may not be used (e.g. “Reboot upon Disconnect”)!
Completing the configuration

The basic configuration of ReachOut is complete once you have made these settings. When the system is restarted next time, it will be configured for the remote diagnosis.

1. Press the “Cancel” or “Esc” key to exit ReachOut. You return to the configuration submenu of ReachOut.

<table>
<thead>
<tr>
<th>Key</th>
<th>Description of configuration submenu</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Exit</td>
</tr>
<tr>
<td>1</td>
<td>Save Setup, Reboot</td>
</tr>
<tr>
<td>3</td>
<td>ReachOut Setup</td>
</tr>
<tr>
<td>5</td>
<td>Disable Reachout at Power On</td>
</tr>
</tbody>
</table>

- Exit configuration menu without saving settings
- Save new configuration and restart control system
- Return to Setup menu
- ReachOut will not be started when the power is next switched on.

Note
Please make sure that the modem is turned on when the remote diagnosis is started.

2. Press key “1” to write the configuration to the PC card and restart. After restart, the remote diagnosis will be available on the MMC 100.2.

Reboot

The configuration menu of ReachOut will not be displayed after rebooting. The PC card is configured and ReachOut will be activated and ready for remote diagnosis every time the control is started.

Note
After an update, the control software of ReachOut must be called again with “3”. Close the configuration software without making any changes. As soon as the configuration menu is displayed, press key “0” and close the configuration menu again. A new menu is displayed which you can close by pressing key “1” (Save Setup, Reboot). Updating the control software might have altered the settings in autoexec.bat and config.sys. Calling the configuration submenu of ReachOut again will update the settings on the PC card.
2.6.3 Activating remote diagnosis later

If the remote diagnosis software is not activated on the host, you can also activate the software after start. The function can be called as a softkey on the MMC 100.2 control.

1. Press softkey “Diagnosis”.
2. Press softkey “Remote diagnosis”. The message “Starting remote diagnosis, restarting control unit; continue with OK” appears.
3. Confirm restart of the control unit by selecting “OK”. ReachOut is activated and the control unit restarted. The NCK is not affected by this process and is not restarted.

2.6.4 Quitting remote diagnosis

Depending on the configuration mode, the function can be quitted as follows:

Mode “Disable ReachOut at Power On” is active:
- HW-Reset of MMC

Mode “Disable ReachOut at Power On” is active:
- Turn off the control system (with POWER ON, remote diagnosis is immediately active in this mode)

2.6.5 Uninstalling the remote diagnosis

Sequence

To uninstall the remote diagnosis software from the MMC 100.2, proceed as follows:

1. Remove the PC card and
2. turn the 0 switch in the card slot to “0”.

2.7 Installing the remote diagnosis software on the PC (viewer)

Preparation

Before you install the remote diagnosis software on your PC, observe the following:

- Determine which viewer version is required. If an MMC 100.2 is used as the host, the DOS version of the viewer must be installed.
- Erase every other remote control software from the PC.
- If you are using a modem, make sure that it is configured correctly and connected to the telephone system.
- Make a note of the modem type, model number and transmission rate.
- Locate the V.24 interface (e.g. COM1 or COM2) to which the modem is connected.
- Determine under which operating system your viewer is operated.

2.7.1 Installing viewer for Windows 95/98/NT4.0

Installation

The software package for the remote diagnosis on the PC is called “Remote diagnosis Viewer 840D”. The supplied installation batch file “SetupW32.bat” can be used to set up the tool on your PC under Windows as follows:

1. Insert the CD into the CD-ROM drive.
2. Select “Run” in the “File” menu in the Program Manager.
3. Type the command line “E:\SetupW32.bat” (“E” is the drive letter for the CD-ROM which can vary).
4. Confirm with “OK”.
5. Follow the further instructions to complete the installation. The steps are the same as required for installation on the control system (see Section 2.4.1).

Click on the Help symbol if you need assistance during installation. The help function is available at all times.

Note

To install the remote diagnosis under Windows NT4.0, administrator rights are required.
2.7.2 Installing viewer for Windows 3.1, Windows for Workgroups 3.11

Installation

The software package for the remote diagnosis on the PC is called “Remote diagnosis Viewer 840D”. The supplied installation program Install.exe can be used to set up the tool from the CD-ROM drive on the PC under Windows 3.x as follows:

1. Insert the CD into the CD-ROM drive.
2. Select “Run” in the “File” menu in the Program Manager.
3. Type the command line “E:\SetupW32.bat” (“E” is the drive letter for the CD-ROM which can vary).
4. Confirm with “OK”.
5. Follow the further instructions to complete the installation. The steps correspond to the steps for installation on the control.

Click on the Help symbol if you need assistance during installation. The help function is available at all times.

Set the viewer options as displayed in the screenshot.
2.7.3 Installing viewer for MS-DOS (required if MMC 100.2 is used as the host)

**Installation**

Use the installation program installd.exe to install the DOS version on the viewer PC:

1. Insert the CD-ROM into the CD-ROM drive.
2. Under Windows 95, 98, NT, change to the MS-DOS prompt to open a DOS window.
3. Change to the directory Dos/Disk1 of the CD-ROM and type “installd.exe". The installation program for the remote diagnosis for DOS is started.

**Note**

For the remote diagnosis of the viewer PC with MMC 100.2, none of the following Windows variants Windows 3.11, 95, 98 NT of the viewer version of the remote diagnosis can be used. Only the DOS variant may be installed. In the above mentioned Windows variants, it can be started in a DOS box.

Background: MMC 100.2 use the DOS operating system.

---

**Installation procedure**

You are guided through the installation routine by a menu-driven menu. Please proceed as follows for a standard installation:

1. Enter your name, company name and serial number in the first screenform of “ReachOut Dos Install”. Confirm your inputs by pressing function key “F10”. Another prompt concerning the correctness of entries is displayed.
2. Confirm your inputs again with “F10” if you are certain that they are correct.
3. Confirm the standard path name by pressing function key “F10”. Screenform “Full (complete) or Custom Installation?” is displayed.
4. Press key “C” to customize the installation. Screenform “Install for Host/Viewer?” then appears.
5. Press key “3” to install the software for the viewer. Screenform “Install for which environment?” is displayed.
6. Press key “2” to install only the DOS version of ReachOut. Screenform “Select Communications” appears.
7. Press key “3” to install communication via modem. The screenform closes and all necessary files are copied onto your computer by the installation routine.
8. During the installation, you will be asked to insert diskette 2 (disk 13). Insert diskette 2 (disk 13) in drive A: and confirm by pressing the “Enter” key. Do the same with diskette 3 (disk 14).
2.7 Installing the remote diagnosis software on the PC (viewer)

**Note**

If you install the program from the CD-ROM, specify the new directory on the CD-ROM as the source when changing the diskette, e.g. with diskette 2, type d:\disk2. Drive letter d: stands for the CD-ROM drive (may vary).

After all files have been copied onto the hard disk, all you need to do is configure the connection. The screenform headed “Type of Modem Support” appears.

9. Press key “1” to configure a connection with an analog modem. Screenform “Enter Computer Name” is displayed.

10. Enter the name of the viewer PC and confirm with “Enter”. This name will be used thereafter for remote diagnosis with ReachOut. Screenform “Communication Settings” is displayed.

11. Configure the modem you have installed in the “Comm Settings” menu.

**Note**

You will find a description of the main configuring steps under configuration of the modem for the host in Section 2.3.3 Configure modem, under paragraph headings “Select COM port”, “Modem type”, “Data transfer rate” and “Phone line type”.

12. Select “File” \(\rightarrow\) “Save Configuration” when you have finished configuring the modem and connection.

13. Press the “Esc” key to close the “Communication Settings” menu. Message box “ReachOut Installation Complete” is displayed.

14. The installation of the remote diagnosis for the viewer is completed.
2.8 Connection setup

2.8.1 General on connection setup with viewer for Win32
(Windows 95/98/NT)

The Windows 32 variant supports connection setup with several computers to or from a single PC.

- A single viewer PC can be connected to several waiting computers. It is possible to use Chat, the Explorer or "RemoteControl" simultaneously or separately.
- A single computer can set up connections under Windows 95/98/NT and wait for connections.

Note
If the control system has no mouse and no "ALT" key, the host on the control system can only be quitted via the viewer.
2.8.2 Connection setup with viewer for Windows 95/98
(MMC 102/103)

Start “ReachOut” under Windows 95. The following window is overlaid:

Click on “Connection” to create a new connection. The input window “Create New Connection” is overlaid.

Enter the name of your connection. The default setting is “My connection”.
In the next input window select the connection type (over which medium the connection is to be set up). The default setting is "Modem".

As an alternative, you can also activate "Network" with TCP/IP protocol if the MMC can be reached over a network, Internet or RAS gateway.

Enter the area code and the telephone number in the last window.

Activate the connection by double-clicking on the symbol that is created in the first screen.
Note
You can adapt the configuration of the modem later using the button "Configure". But in this case, the settings you have made will be other than those made in the dialog box "Control Panel/Modems/Properties".

Connection setup with viewer via network (TCP/IP)

Use the same procedure as with a modem connection until the bottom box appears.

Select “Network”.

Enter the IP address of the remote computer you want to be connected to under “Remote computer’s name”.

© Siemens AG 2000. All rights reserved
SINUMERIK 840D/840Di/810D/FM-NC Extension Functions (FB2) – 04.00 Edition 2/F3/2-89
2.8 Connection setup

Connection setup with viewer via Internet

Start the long-distance data transmission network (LDDT) by double-clicking on the folder “My Computer” or use “Start” → “Programs” → “Accessories” → “Communications”.

Create a new connection by double-clicking on the “Make New Connection” icon. On the viewer side perform the steps that are listed under Section 2.3.6 up to and including “Integration into the MMC user interface”. A second icon is displayed with the default name “My Connection” or the selected name. Activate the connection by double-clicking on the appropriate icon.

If dial-up networking and the Internet connection have been set up on the MMC 103, you can set up the remote diagnosis connection over network (TCP/IP), as described under “Connection setup with viewer over network (TCP/IP)”. Use the IP address that was dynamically assigned to the MMC 103 if available.
2.8.3 Connection setup with viewer for Windows NT (MMC 102/103)

Configuration as gateway
Several controls are connected with a Windows NT computer via a network. You can access the NT computer host from any viewer PC via modem or ISDN. Using the NT viewer you can operate one of the MMC103 hosts from the NT computer host.

Preparations
No additional configuration is required on the individual controls. All controls must be configured as described under a network.

The first viewer PC from which the connection is to be set up to the individual controls must be a Windows NT computer.

Install the remote diagnosis software ReachOut for Windows NT on the computer. In general, installation, configuration and operation are conducted in the same way as for Windows 95.

Configure the individual connections via “Connection”, “New connection”. Enter the name of the new connection and select the type of connection. Enter the telephone number or IP address according to the type and click on “Finish”.

Under “Configure”, “Options” select the desired connections and configure them. At least two types of connections must be set up.
The entry “NetBIOS” should not be enabled. Enable “When computer starts” if the remote diagnosis function is to be started automatically at system boot.

**Connection setup**

Power up the Windows NT computer and start the remote diagnosis software. Dial up the Windows NT computer from a second PC which also has the remote diagnosis software installed on it. Once the connection has been set up, you can access other possible connections from the NT computer too.

**Note**

The connection between the viewer PC and NT computer must be different from the connection between the NT computer and the control. A modem can only set up one connection.
2.8.4 Connection setup with viewer for Windows 3.1X (MMC 102/103)

Start Windows 3.1X. In the Program Manager click on the icon “ReachOut” and on “ReachOut Viewer” in the overlaid window.

Start the remote diagnosis via “Remote Control”.

Select the desired subscriber and click on “OK” to establish the connection.

You can add other customer entries by clicking on “Add” and change the entries via “Edit”.

- **Password (Optional)**: **********
- **Password Verification (Optional)**: **********
- **Terminal Emulation Entry**: [ ]
2.8.5 Connection setup with viewer in MS-DOS (MMC 100.2)

The MMC 100.2 is based on the MS-DOS operating system. The ReachOut software for the viewer is also available as an MS-DOS program. If you use a Windows operating system on the viewer PC, you must use the DOS version of the remote diagnosis.

Connection setup in MS-DOS

To set up the connection between the viewer and host via a modem, please proceed as follows:

1. Start ReachOut under MS-DOS or from the DOS prompt of Windows by calling the file gvm.bat from the ReachOut directory. ReachOut for the viewer is loaded.

2. Choose “Connect using Phone book” from the “Link” menu. Every entered host is displayed with name and telephone number.

3. Select the host of your choice from the list using the cursor keys and confirm by pressing the “Enter” key. The host is selected.

Or:

1. Choose “Contact to Host PC” from the “Link” menu. Screenform “Enter Phone Number for Host PC” is displayed.

2. Enter the telephone number of the desired host and confirm by pressing the “Enter” key. The host is selected.
2.9 Functions of the viewer PC, version Win32

ReachOut main screen of the Win32 version:

The new version does not contain any additional functions. But there are some improvements, compared with older versions.

Improvements

1. The remote diagnosis can now display even 24-bit truecolor (to be set on the host) on the viewer.

2. Under WinNT, a connection can be established only with appropriate user rights. With earlier versions, this was not possible under WinNT.

2.9.1 Remote control

In “Remote Control” mode, you can see the screen of the MMC 102/103 on your PC screen and operate the MMC using mouse and keyboard. You can activate softkeys by double-clicking on them with the mouse or by means of the function keys. With the horizontal softkeys, SK1 to SK8 correspond to function keys F1 to F8, “Recall” corresponds to F9 and “Operating area switchover” to F10. The vertical softkeys are reached, starting from the top, by means of Shift + F1 to Shift + F8. You can operate all areas of the MMC 102/103 from the viewer PC.
### Disconnecting

To break off the connection, simultaneously press the left and right Shift keys on the viewer. The remote diagnosis screen is overlaid (Windows 3.1, 3.11). Click on the disconnect symbol and confirm that you want to hang up in the next window. The control remains ready to receive so that the connection can be set up again. Select the icon that is relevant to this connection for Windows 95/NT and right mouse-click on it. Activate the "Disconnect" menu command from the overlaid menu.

**Note**

If the control system has no mouse and no "ALT" key, the host on the control system can only be quitted via the viewer.

### 2.9.2 File transfer

**What does file transfer do?**

The file transfer function makes it possible to exchange files between the viewer PC and the control. In this case, the viewer PC is referred to as the "Local" and the MMC 102/103 as the "Host". The transmission rate is approximately 6–8 minutes for 1 MB at 9.600 baud.

**How to cancel the function**

You can return to the remote diagnosis selection screen by activating "Exit" in the "File" menu or by means of the key combination Alt + F4.
2.9.3 Chat for MMC 102/103 (communication via text input window)

Chat screen under Windows 95
The chat window allows both operators to communicate by typing in text at the same time. Click on "Chat" to open the Chat window.

![Chat window](image)

**Note**
On the MMC keyboard you can select “Chat” via the End key and activate it with the Input key.
While a connection is active, you can select the main screen on the MMC via “Diagnosis” → “Remote Diagnosis”.

Exiting the function
The Chat window is closed with “Exit”.

**Note**
This is not possible on the MMC without the MFII keyboard. In this case, the operator on the viewer side must close the Chat window and the window on the MMC is then closed automatically.
2.9.4 Terminal emulation

This function is not required for remote diagnosis.

2.9.5 Exit

You can leave the menu by activating “Exit”. The program is terminated only if the connection has been ended beforehand.

2.9.6 Help

A comprehensive help menu is available to assist at every important stage of operation.
2.10 Functions of viewer PC, version Win16

ReachOut main screen with Windows 3.X:

ReachOut main screen with Windows 3.X:
2.10.1 Remote control

Operating the MMC 102/103

In “Remote Control” mode, you can see the screen of the MMC 102/103 on your PC screen and operate the MMC using mouse and keyboard. You can activate softkeys by double-clicking on them with the mouse or by means of the function keys. With the horizontal softkeys, SK1 to SK8 correspond to function keys F1 to F8, “Recall” corresponds to F9 and “Operating area switchover” to F10. The vertical softkeys are reached, starting from the top, by means of Shift + F1 to Shift + F8. You can operate all areas of the MMC 102/103 from the viewer PC.

Disconnecting

To break off the connection, simultaneously press the left and right Shift keys on the viewer. The remote diagnosis screen is overlaid (Windows 3.1, 3.11). Click on the disconnect symbol and confirm that you want to hang up in the next window. The control remains ready to receive so that the connection can be set up again. Select the icon that is relevant to this connection for Windows 95/NT and right mouse-click on it. Activate the “Disconnect” menu command from the overlaid menu.

2.10.2 File transfer

What does file transfer do?

The file transfer function makes it possible to exchange files between the viewer PC and the control. In this case, the viewer PC is referred to as the “Local” and the MMC 102/103 as the “Host”. The transmission rate is approximately 6 – 8 minutes for 1 MB at 9,600 baud.

How to cancel the function

You can return to the remote diagnosis selection screen by activating “Exit” in the “File” menu or by means of the key combination Alt + F4.
2.10.3 Chat for MMC 102/103 (communication via text input window)

Chat screen under Windows 3.11

The chat window allows both operators to communicate by typing in text at the same time. Click on "Chat" to open the Chat window.

Note

On the MMC keyboard you can select "Chat" via the End key and activate it with the Input key. While a connection is active, you can select the main screen on the MMC via “Diagnosis” → “Remote Diagnosis”.

Exiting the function

The Chat window is closed with "Exit".

Note

This is not possible on the MMC without the MFII keyboard. In this case, the operator on the viewer side must close the Chat window and the window on the MMC is then closed automatically.
2.10.4  Terminal emulation

This function is not required for remote diagnosis.

2.10.5  Exit

You can leave the menu by activating “Exit”. The program is terminated only if the connection has been ended beforehand.

2.10.6  Help

A comprehensive help menu is available to assist at every important stage of operation.
2.11 Function of viewer PC (MMC 100.2)

The remote diagnosis for the MMC 100.2 provides the same functions as for the MMC 102/103. However, the Chat function is restricted in the MMC 100.2 version. Communication is only indirectly possible via a part program.

2.11.1 Remote control

Operation of the MMC 100.2

In "Remote control" mode, the screen contents on the MMC 100.2 (host) appears on your screen. You can control the host functions via the viewer PC keyboard. In this instance, softkeys are activated via function keys. Horizontal softkeys SK1 to SK8 are operated via function keys F1 to F8. Vertical softkeys are operated from top to bottom via Shift + F1 to Shift + F8. “Recall” represents function key F9 and “Operating area switchover” F10. In other words, you have control over all host functions from the viewer PC.

Clear the connection

If you wish to clear the connection between the viewer and host, you must press the left-hand and right-hand shift keys together. The window is closed and you return to the ReachOut interface.

In ReachOut, change to the menu “Link” → “Disconnect from Host-PC”. The connection to the MMC 100.2 is ended.

Note

With older MMC versions (< SW 5), the function “Hardware rely” must possibly be enabled in the viewer under “Preferences→Keyboard Handling”.

2.11.2 File transfer

Meaning
File transfer allows you to transfer data from the viewer to the host and from the host to the viewer. The transferred data are stored in the clipboard on drive e:\ on a host with MMC 100.2. A directory named “transfer” is provided for this purpose on drive e:\.

Transfer of data
To transfer data you must open the File Manager:
1. Select “File” --> “Invoke File Manager” on the ReachOut interface. An Explorer with two windows is opened.

   The directory of the viewer PC is displayed in the left-hand window of the Explorer. The host directory is displayed in the right-hand window. Files can be copied and moved between the host and viewer or deleted. Files can only be written to drive e:\ on the host. All other drives have read status only.

2. Close the File Manager by selecting “Exit” --> “Yes”. You then return to the ReachOut interface.

Transfer directory
The transfer of data between the viewer and host is organized via a transfer directory. Data from the viewer or host are stored initially in this directory. To transfer part programs, for example, the data are copied into the transfer directory from the viewer PC where they can then be processed from the host.

To call data stored in the transfer directory from the host, proceed as follows:

1. Select softkey “Services” on the host. A new screenform appears.

2. Select softkey “Clipboard”.

3. Select softkey “Transfer directory”. The transfer directory is opened.

The functions “Copy and Paste”, “Create archive”, “Delete” and “Refresh-Dir” are available on the vertical softkeys.
2.11.3 Chat

**Meaning**

Direct CHAT is not supported. The Chat function is possible for the MMC 100.2 only with restrictions if first a part program, such as CHAT1.MPF, is edited in a remote diagnosis session. This part program should be deleted at the end of the session.

---

**Caution**

Do not start the CHAT function from the remote diagnosis menu!
Supplementary Conditions

3.1 General supplementary conditions

Availability of the function

The function “Remote diagnosis” is available for:

- SINUMERIK 840D with MMC102/103, SW 3.1 and higher
- SINUMERIK 840D with MMC100.2, SW 5.1 and higher

The following is not supported:

Remote diagnosis

- up to SW 4: Windows 98
- up to remote diagnosis SW 4: AGP graphics cards
3.1 General supplementary conditions

Notes
Tips and Tricks

This Section contains some helpful tips and tricks that might be useful.

4.1 Cascading of Win-Viewer to the DOS-HOST via “Gateway”

A connection to the control system can be established to several computers using remote diagnosis V5.1 ⇒ cascading.

To do so, the viewer version of the remote diagnosis must be installed on all computers, with exception of the control system. The remote diagnosis software on the intermediate computers in the direction towards the control system operate as a viewer and in the direction towards the end viewer as a host, which must be set to the Wait state.

The cascading always starts from the control system and then successively continues from one intermediate computer to the next to the end viewer.

It is also possible to cascade between different operating systems. The cascading of a Win32 viewer to a DOS host is shown below. For obvious reasons, different communication links must be used for viewer and host on the intermediate stations. The example below shows the intermediate computer directly connected to the end viewer via a TCP/IP network and directly to the control system via RS232. It is also possible to use the other admitted communication links.
4.1 Cascading of Win-Viewer to the DOS-HOST via “Gateway”

Fig. 4-1 Cascading the remote diagnosis via a gateway
4.1 Cascading of Win-Viewer to the DOS-HOST via “Gateway”

The following possibilities were tested and have been found to be operative.

<table>
<thead>
<tr>
<th>Machine</th>
<th>Operating system</th>
<th>ReachOut version</th>
<th>Supplementary conditions</th>
</tr>
</thead>
<tbody>
<tr>
<td>MMC 100.2</td>
<td>MS-DOS</td>
<td>DOS host</td>
<td>No</td>
</tr>
<tr>
<td>Gateway PC (1)</td>
<td>Win95/98</td>
<td>DOS viewer + Win32 host V4.1/V5.1</td>
<td>The DOS viewer must run in a DOS window (no fullscreen)</td>
</tr>
<tr>
<td>Viewer PC (2)</td>
<td>Win95/98 NT</td>
<td>Win32 viewer V4.1/V5.1</td>
<td>First the connection MMC 100.2 ↔ gateway PC must be established before this connection may be established.</td>
</tr>
</tbody>
</table>

**Caution**

The Win NT operating system may not be run on the gateway PC (1). This mode does not allow 16-bit graphics resolution of the DOS viewer in a DOS window.
4.2 Automated installation of remote diagnosis

For remote diagnosis V5.1, installation scripts, such as the Windows Notepad, can be created for automated installation. If different users require different installation routines, several files can be created, whereby these must be started specifically in the Windows command line by specifying the file name of the script after the setup command.

If the same installation routine is sufficient for all users, you should create a script file with the name “ROINST”, which is automatically executed by the SETUP.EXE file and therefore need not be specifically initiated by the user. The script “ROINST” must be stored in the same directory as the setup programs to ensure that this file can be called automatically.

Note

To provide completely automated installation, you should copy all installation disks from the CD-ROM to a network drive or to diskettes. The installation script created can then be stored on the first diskette. Furthermore, the SETUP.ISS file that is contained on the first diskette must be adapted as described in this Section.

If special script names are used, the SETUP program must be started with the attribute “SCRIPT = Script name”.

The following syntax applies to the SETUP command:

```
SETUP [TYPE = [HOST | VIEWER] [: PUBLIC | SHARED] [SCRIPT = script filename] [script parameter 1] [script parameter 2] ... [script parameter n]
```

In this case, the command line would be used for starting the setup with the script file “HOST” which will contain the settings for installing the host version of remote diagnosis:

“SETUP SCRIPT=HOST”

Note

Under WinNT, this parameter only applies to version 8.30 or higher.
Creating an installation script

1. Use a text editor to create a new file
2. Type the desired script commands and settings in the file.

When creating the script for a network installation, make sure that the parameter PUBLIC is not deleted; otherwise, you will have no safety during the entire installation of the remote diagnosis.

3. Save the file.

If you wish the script to be started automatically during the remote diagnosis, the script file must be called "ROINST" (without file extension) and be saved in the same folder as the setup program.

---

**Note**

Make sure that the HIDDEN switch for settings to be removed from the SETUP.ISS file is set in the installation script. Otherwise, you must enter these values in dialog boxes.

---

**Parameter list**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTOSTARTHOST</td>
<td>yes/ no</td>
<td>determines whether the remote diagnosis is set to the host wait mode automatically during start.</td>
</tr>
<tr>
<td>COMPANYNAME</td>
<td>siemens</td>
<td>specifies the name of the company for which the remote diagnosis is licensed. If you do not want to specify a company name, use &quot;COMPANYNAME=&quot;.</td>
</tr>
<tr>
<td>CONNSHORTCUTS</td>
<td></td>
<td>Use this command to create shortcut icons for all remote diagnosis link icon files (*.RCO) that have been found in the [DISK1] folder during installation.</td>
</tr>
<tr>
<td>EXECUTE</td>
<td>program_name</td>
<td>starts the program with the name &quot;program_name&quot; after the installation of the remote diagnosis has been completed and Windows has been restarted.</td>
</tr>
<tr>
<td>GROUP</td>
<td>folder_name</td>
<td>specifies the name of the folder that will contain the remote diagnosis icons. If the GROUP command is missing, Setup will create a folder with the default name &quot;ReachOut&quot;.</td>
</tr>
<tr>
<td>GROUP_ID</td>
<td>group_ID</td>
<td>(only available from version 8.3 onwards.) specifies the name of the remote diagnosis group to which the computer belongs in a NetWare or Banyan VINES network.</td>
</tr>
</tbody>
</table>
### HIDDEN

Hides the display of the installation process on the display.

If an installation script is processed using this command, a search for required parameters is carried out in the SETUP.ISS file contained in the same folder. Certain installation parameters in this file do not have default values; they must therefore be specified by the user.

Parameters in the SETUP.ISS file, for which values must be specified:

- **AdminName**: User name for the initial user of the remote diagnosis with administrator rights. **Important**: Users who install the remote diagnosis with these parameters must know the assigned name.
- **AdminPass**: Password for the initial user with administrator rights for the application. **Important**: Users who install the remote diagnosis with these parameters must know the assigned name.
- **SzName**: A name that is stored in the Windows registry of the remote diagnosis.
- **SzCompany**: The company name that is stored in the Windows registry of the remote diagnosis.
- **SzSerial**: The serial number of the remote diagnosis, which is stored in the Windows registry of the remote diagnosis.

These values are used on all computers on which the remote diagnosis is installed.

### ICONS=icon,icon_description

Places the shortcut icons in the ReachOut program folder. After installation, these shortcuts are to be found in the Windows “Start” menu.

If you do not wish to use these icons, use “ICONS=” or use the “NOGROUP” command.

**Example:**

`ICONS=REACHOUT.EXE,ReachOut;REACHOUT.HLP,ReachOutHelp;ROUSERS.EXE,ReachOut User Manager;`
### 4.2 Automated installation of remote diagnosis

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOCALLOGON</td>
<td>defines whether users must log into the remote diagnosis when starting the remote diagnosis. (only available from version 8.02 onwards.)</td>
</tr>
</tbody>
</table>
| NAME=computer_name      | defines the name used for the remote diagnosis to identify the computer on which the remote diagnosis is installed.  
If you do not wish to use a name, type “NAME=”. |
| NODESKTOPICON           | (only available from version 8.02 onwards.)                                                      |
| NETWORK=protocol        | defines the network type via which the remote diagnosis can communicate. You can define more than one network if you use the command “NETWORK” several times.  
**Example:**  
NETWORK=Winsock  
NETWORK=NetBios  
**Parameter values that can be used:**  
- Banyan – Banyan Vines network  
- IPX – Novell Netware SPX or IPX using the Broadcast communication (the same as with SPX)  
- NetBios – NetBios networks  
- IPX – Novell Netware SPX or IPX using the SAP communication  
- IPX – Novell Netware SPX or IPX using the Broadcast communication (the same as with IPX)  
- Winsock – TCP/IP networks, including the Internet |
| NOGROUP                 | has the effect that no Windows program folder is created for the remote diagnosis in the Start menu. |
| PUBLIC                  | installs only the configuration files of the remote diagnosis. The remote diagnosis is started from the folder (usually a network or a shared folder) from which it was installed.  
**Tip:** Make sure that the remote diagnosis is installed in the source folder completely. The parameter Public cannot be used when the program is installed from disks. |
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>REM</td>
<td>identifies a comment line that is not processed by the remote diagnosis.</td>
</tr>
<tr>
<td>RESTARTWINDOWS</td>
<td>exits Windows and restarts it after installation.</td>
</tr>
<tr>
<td>SERVER</td>
<td>defines the name of the NetWare server with which the remote diagnosis is to be linked. If the remote diagnosis is installed on a computer not integrated into the network, this parameter will have no effect.</td>
</tr>
<tr>
<td>SHARED</td>
<td>installs the remote diagnosis as a shared program. A shared installation is a central copy from which safety settings for all users can be made, who have carried out a Public installation from the shared copy. The shared installation is usually carried out on a shared network drive.</td>
</tr>
<tr>
<td>TARGET</td>
<td>defines the folder in which the remote diagnosis is to be installed. If this parameter is omitted from the script, the remote diagnosis is automatically installed in the folder “C:\PROGRAM FILES\REACHOUT” provided that the path “C:\PROGRAM FILES” exists. Otherwise, the user will be prompted to specify a folder name.</td>
</tr>
<tr>
<td>TYPE=Viewer/Host</td>
<td>defines whether a computer does calls or waits for calls from remote computers.</td>
</tr>
</tbody>
</table>
### 4.2 Automated installation of remote diagnosis

<table>
<thead>
<tr>
<th><strong>USERNAME</strong>=username</th>
<th>specifies the name of the person for whom the remote diagnosis is licensed. Tip: This is not the user name assigned with a password entry.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>WAITON</strong>=protocol</td>
<td>(only from version 8.02 onwards); defines the connection types via which the remote diagnosis expects a call in advance. You can specify several connection types. Example: WAITON=SXP;TELEPHONY;WINSOCK Parameter values that can be used: Banyan – Banyan Vines networks CAPI = CAPI connection DIRECT – direct connection or zero modem cable NetBios – NetBios networks IPX – Novell Netware SPX or IPX using the Broadcast communication (the same as with IPX) TELEPHONY – modem WINSOCK – TCP/IP networks including Internet</td>
</tr>
</tbody>
</table>

REMOTE DIAGNOSIS (F3)
Example of a script

REM installation script “ROINST"
AUTOSTARTHOST=no
COMPANYNAME=SIEMENS AG
CONNSHORTCUTS
EXECUTE=C:\MyBatchfile.BAT
GROUP=remote diagnosis
REM GROUP_ID=group_ID
HIDDEN
REM
ICONS=REACHOUT.EXE,ReachOut;REACHOUT.HLP,ReachOut-Help;ROEVE
NTS.EXE,Event Viewer;ROUSERS.EXE,UserManager;
ROSCRUI.EXE,Automating;SUPPORT.WRI, SUPPORT;
README.WRI,ReadMe;C:\Windows\uninst.exe -fC:\remote
diagnosis\DeIsL1.isu-cC:\remote diagnosis\ROUInst.DLL,UnInst;
REM LOCALLOGON=yes or no
NAME=ExampleComputer
REM NODESKTOPICON
NETWORK=Winsock
REM NOGROUP
REM PUBLIC
RESTARTWINDOWS
SERVER
REM SHARED
TARGET=C:\remote diagnosis
Type=Viewer
USERNAME=Mustermann
WAITON=Winsock

Using this script, the remote diagnosis will be installed as a viewer/host with the company name “SIEMENS AG”, the user name “Mustermann”, the computer name “ExampleComputer” in the folder “C:\remote diagnosis” and will create the entry “remote diagnosis” in the START menu. The installation is carried out completely hidden in the background. The user need not carry out any entries. This is done by the command “HIDDEN”. The required data, such as the user name of the initial user with administrator rights, the corresponding password and also the serial number are to be found in the file SETUP.ISS. The default values in this file can be modified and the serial number be inserted (see example).
Example of a SETUP.ISS file

; This script runs only in conjunction with a regular ReachOut installation script that contains the “HIDDEN” command. If the “HIDDEN” command is not specified, this SETUP.ISS file is ignored.
;
; This script will install ReachOut. You must restart the computer manually before using ReachOut.
; Changing BootOption=0 to BootOption=3 will cause an automatic restart.
;
; To use this script you _must_ modify the AdminName=, AdminPass=, szName=, szCompany=, and szSerial= lines below and provide valid entries. szName and szCompany cannot be empty, and szSerial must be a valid number or the installation will not complete.

[InstallShield Silent]
Version=v3.00.000

szDir=C:\Program Files\ReachOut
Result=1

[SdSelectFolder-0]
szFolder=ReachOut
Result=1
4.2 Automated installation of remote diagnosis

After installation, the computer is rebooted, and the batch file “MyBatchfile.BAT” (it could also be an EXE file) is executed. Since the command “ICONS” is provided with comments, all icons of the remote diagnosis will be created. If certain icons are not created, remove the comment mark “REM” before the “ICONS” and the appropriate entries for the icons.

Note

If the icon “Uninst” is created using the “ICONS” command, the inverted commas must be removed from the string of the shortcut for the icon in the Properties; otherwise, the UNINSTALL.EXE will not be found.

The host is configured such that it is not automatically set to the Wait status after starting the remote diagnosis. It must be started manually with “Winsock” (TCP/IP, incl. Internet) set as the default setting.
4.3  Adapting the Remote Diagnosis window

In most cases, the Remote Diagnosis window on the MMC is hidden by the header. To adapt the window, it is possible to specify size and position of the window via the registry file.

Sequence

1. Boot the MMC in Windows Service Mode.
2. In Notepad, type the following text:

   ```plaintext
   REGEDIT4
   [HKEY_CURRENT_USER\Software\Stac\ReachOut\Reachout]
   "X"=dword:00000001
   "Y"=dword:000000bc
   "Width"=dword:000019a
   "Height"=dword:00000f
   ```

3. Save this as a file with the extension ".reg".
4. Now, start the Explorer and start the created file by double-clicking on it. The position and size specifications will be entered in the Registry. When the remote diagnosis is started next time, it is positioned and proportioned according to the values entered above.

If size and position do not correspond to your wishes, you can adapt the values accordingly. The values must be specified as hexadecimal values.
### 4.4 Repeated restart request

After the remote diagnosis has been installed, it can occur that a restart is required although Windows has already been restarted.

This behavior can be caused by the file “REBOOT” in the ReachOut directory. To eliminate this problem, use the Explorer to delete this file.
4.5 Tips for solving this problem with modem connections

**Modems_e.wri** Tips for eliminating problems with modem connections under Windows are to be found in the file “Modems_e.wri” on the CD-ROM in the directory “siemens/Tipps”.

4.6 Blue screen after booting when the connection is established for the first time

The “blue screen” that appears after booting when establishing an RO connection for the first time; the following message appears:

Invalid VxD dynamic link call from ROVxD(01) + 000A3A8 to device 000C, service 3 ....

can be bypassed by disabling the cursor.
This can be done as follows:
1. Boot in Windows Service Mode
2. Edit the “system.ini” in the directory “C:\Win95"
3. Comment the following entries with “;“:
   a. Section:
      [boot] ...
      ;mouse.drv=mouse.drv
   b. Section
      [386Enh] ...
      mouse=*vmouse
4. Save the file and save the computer via Start → Shut down ... and “Y” “Y”:

Another possible problem solution is the installation of a serial mouse in Windows Service Mode.

The “blue screen” that appears after booting when establishing an RO connection for the first time; the following message appears:

Invalid VxD dynamic link call from ROVxD(01) + 000CC00 to device 001D, service 11 ....

is bypassed by loading a new keyboard driver. To overcome the problem, the MMC software must be upgraded to MMC V04.04.24.

■
Signal Descriptions

No signals are required at the NCK-PLC interface for this function.

Example

– None –

Data Fields, Lists

No signals or machine data are required for this function.

7.1 Alarms

A more detailed description of the alarms which may occur is given in

References: /DA/, Diagnostic Guide

or in the online help in systems with MMC 102/103.

Brief Description

Setting up machine

Even on modern, numerically controlled machine tools, a facility must be provided that allows the operator to traverse the axes manually. This is especially necessary when a new machining program is being set up and the machine axes have to be moved with the traversing keys on the machine control panel or with the electronic handwheel. Where coordinate offset or rotation is selected, handwheel jogging can even be performed in the transformed workpiece coordinate system.

Retraction of tool

After a program interruption caused, for example, by NC-STOP, RESET or power failure, the machine operator must retract the tool manually from its current machining position. This is usually done by operating the traversing keys in JOG mode. The transformations and coordinate systems used for machining must be activated while this is done.

Contents

The following Description of Functions illustrates the options and characteristics associated with the JOG traverse mode.

- Continuous jogging in jog or continuous mode (in JOG)
- Incremental jogging (INC) in jog or momentary-trigger mode (in JOG)
- Traversing the axes using electronic handwheels (accessories) (in JOG)
- Handwheel override in AUTOMATIC (path setting and velocity override)

DRF

The differential resolver function generates an additional incremental zero offset in AUTOMATIC mode via the electronic handwheel. With this function it is possible, for example, to compensate for tool wear within a programmed block.
Detailed Description

2.1 General

2.1.1 General characteristics of manual traverse in JOG

The following is a description of the characteristics which generally apply to JOG mode (irrespective of the type selected).

**JOG mode**

JOG mode must be active if the axes are to be traversed manually (referred to as “Manual traverse” below). The PLC receives the interface signal “Active mode: JOG” (DB11, DBX4.2) when the operating mode is activated.

*References:* /FB/, K1, “Mode Group, Channels, Program Operation Mode”

**Machine functions**

There are several JOG variants (so-called “machine functions”) within the JOG mode:

- Continuous jogging (JOG CONT)
- Incremental jogging (JOG INC)
- Jogging with the handwheel

**Handwheel operation**

The handwheel operation is also active with the following functions:

- Operating mode JOG-REPOS for moving the geometry and machine axes
- Operating mode AUTOMATIC, for moving out a DRF displacement
- with path override
- when moving the backlash point of an oscillation

The machine function is selected via the PLC interface. A separate PLC interface exists for both the machine axes (axis-specific) and the geometry axes (channel-specific).

**Simultaneous traversal**

All axes can be traversed simultaneously in JOG.

There is no interpolation between several axes traversed simultaneously.
Velocity

The velocity for JOG traversal is determined by the following value settings depending on the feed mode:

- When linear feedrate (G94) is active (SD: JOG_REV_IS_ACTIVE (revolutional feedrate in JOG) = 0):
  - with general SD: JOG_SET_VELO (JOG velocity with G94) or
  - for rotary axes
    with the general SD: JOG_ROT_AX_SET_VELO (JOG velocity for rotary axes)
  - or with axis-specific MD: JOG_VELO (jog velocity), only if SD: JOG_SET_VELO = 0.

- When revolutional feedrate (G95) is active (SD: JOG_REV_IS_ACTIVE (revolutional feedrate in JOG) = 1):
  - with general SD: JOG_REV_SET_VELO (JOG velocity G95)
  - or with axis-specific MD: JOG_REV_VELO (revolutional feedrate in JOG), only if SD: JOG_REV_SET_VELO = 0.

The default setting for feedrate velocity is mm/min and for revolutional feedrate rpm.

Rapid traverse override

If the rapid traverse override key is pressed at the same time as the traversing keys, then the movement is executed at the rapid traverse velocity set in axis-specific MD: JOG_VELO_RAPID (axis velocity in JOG mode with rapid traverse override) (or in the case of revolutional feedrate, set in MD: JOG_REV_VELO_RAPID).

Feedrate override

The velocity at which axes traverse in JOG can also be influenced by the axial feedrate override switch provided that interface signal “Axial feedrate override active” (DB31, ... DBX1.7) is set.

The assignment of percentages to the individual settings of the feedrate override switch is programmed via machine data. At switch position 0% the axis is not traversed if 0 has been entered in the associated machine data. IS “Axial feedrate override active” has no meaning at switch position 0%.

Instead of the position on the feedrate override switch (Gray code), the value in percent (0% to 200%) can be set by the PLC. Again, the selection is made via the machine data.

References: /FB/, G1, “Feeds”

Acceleration

Acceleration in manual traverse mode also takes place according to a programmed acceleration characteristic. The acceleration characteristic applicable in JOG mode for a single axis is defined in MD: AX_JERK_DEFAULT (initial setting of axial jerk limitation).

Display
The JOG basic display appears on the screen when JOG mode is selected. This basic display contains the position, feedrate, spindle and tool values. For information about the individual displayed values see:

References: /BA/, Operator's Guide

Coordinate systems
The operator has the option of traversing axes in different coordinate systems in JOG mode. The following coordinate systems are available:

- Basic coordinate system; each axis can be traversed manually
- Workpiece coordinate system; only geometry axes can be traversed manually (channel-specific)

Geometry axes
In JOG traversing mode, an axis can be traversed as either a machine axis (axis-specific) or as a geometry axis (channel-specific). The characteristics of the machine axes are dealt with in the following description. The special features of traversing geometry axes in JOG mode are described in more detail in Section 2.8.1.

Manual traversal of spindle in JOG
Spindles can also be traversed manually in JOG mode. Essentially the same conditions apply as for manual traverse of axes. Spindles can be traversed in JOG mode using the traverse keys continuously or incrementally, in continuous-trigger or momentary-trigger mode, or with the handwheel. The mode is selected and activated via the axis/spindle-specific PLC interface as for the axes. The axis-specific machine axes also apply to the spindles. The special features of traversing spindles manually are described in more detail in Section 2.8.2.
2.1.2 Control of JOG traverse functions via PLC interface

**MMC/NCK/PLC interface**

Most individual functions required for manual traversal in JOG are activated via the PLC user interface. The machine-control manufacturer can adapt the JOG mode functions to the machine tool through the PLC user program depending on the configuration of the NC system.

**Machine control panel**

The signals between the machine control panel and the individual PLC/NCK interface data blocks are transferred by the PLC user program on a machine-specific basis. The PLC user programs define the assignment of the direction keys on the machine control panel to the axis/spindle (machine axes, geometry axes) traversing keys.

The following machine control panel signals are of particular importance to manual traverse:

- JOG mode (selection)
- Machine function INC1 ...
- Direction keys
- Feedrate override and spindle speed override

For further information on signals sent from the machine control panel see:

**References**: /FB/, P3, “Basic PLC Program”

**Selection of machine function**

The machine functions available in JOG mode can be selected from the following locations:

- From the machine control panel e.g. user DB interface
- From the PLC user program PLC/NCK interface

The PLC user program transfers the machine function pending at the machine control interface to the relevant PLC/NCK interface. The axis-specific NCK/PLC interface (DB 31, ... signals see Section 5.3) is used for a machine axis/spindle and the channel-specific NCK/PLC interface (DB21, ... signals see Section 5.2) is used for a geometry axis.
2.1.3 Control response at power On, mode change, reset, block search, repositioning

Any reset yields an abort with braking ramp of a traversing movement triggered by handwheel operation.

Selection of MCP

The following example shows the sequence of operations for selecting the “continuous” machine function for a machine axis of the machine control panel.

Fig. 2-1 Sequence of operation for selecting a machine function from the machine control panel

Sequence of operation

1. The operator selects the machine function “Continuous JOGGING” on the machine control panel for a machine axis.

2. IS “Machine function”
   The PLC program (basic and user program) logically combines this IS and sends the request “Machine function continuous” (DB31, ... DBX5.6) to the NCK interface.
   Before this happens, the PLC user program first checks that this request is permissible with regard to the current machine status.

3. IS “Active machine function”
   The control selects the machine function internally. As soon as the machine function “JOG continuous” is active (DB31, ... DBX65.6), a signal is returned from the NCK to the PLC.

For further information on signal transmission between the machine control panel and the PLC see:

References: /FB/, P3, “Basic PLC Program”
2.2 Continuous jogging

Selection
Continuous mode in JOG mode is selected via the PLC interface (IS “Machine function: Continuous” (DB21-28 DBX13.6, ff)). As soon as continuous mode is active, a signal is returned to the PLC with IS “Active machine function: Continuous” (DB21-28 DBX41.6, ff).

Traversing keys +/- The “plus” and “minus” traversing keys are selected to move the relevant axis in the appropriate direction. If both keys are pressed at the same time no movement takes place or a moving axis is stopped.

Important
When the control is switched on, axes can be traversed to the limits of the machine because they have not yet been referenced. Emergency limit switches might be triggered as a result.

The software limit switches and the working area limitation are not yet active.

Travel command +/- As soon as a traverse request for an axis is active (e.g. after selection of a traverse key), the IS “Travel command+” or “Travel command-” (DB21, ..., DBX40.7 or DBX40.6) is sent to the PLC (depending on selected traverse direction).

2.2.1 Distinction between jog mode and continuous mode

Selection
In JOG mode we distinguish between traversing in jog mode and continuous mode. The selection is made in the general SD: JOG_CONT_MODE_LEVELTRIGGRD (JOG continuous in jog mode) and is active for all axes.

Default setting
Jog mode is the default setting.

Continuous traversal in jog mode

Function
In jog mode (default setting) the axis traverses for as long as the traverse key is held down if no axis limitation is reached first. When the traverse key is released the axis is decelerated to zero speed and the movement comes to an end.
Continuous traversal in continuous mode

Function

When the traverse key is pressed and released (first rising edge) the axis starts to traverse at the set velocity in the desired direction. This movement is continued after the traverse key is released. The movement of the axis is either stopped by the operator or because of a response in the control (e.g. software limit switch reached).

Warning

If “continuous” mode is selected, several axes can be started by pressing and releasing the relevant direction key. Any interlocks must be implemented via the PLC!

Interrupt traversing movement

The operator can use the following methods to interrupt the traversing movement:

- Set feedrate override to 0%
- Axial feed disable (PLC interface signal)
- NC STOP or NC STOP axis/spindle

If the cause of the interruption is removed again, the axis continues to traverse.

Abort traversing movement

The traversing movement can be stopped and aborted by means of the following operator inputs or monitoring functions:

- Same traverse key pressed again (second rising edge)
- Traverse key for the opposite direction pressed
- RESET
- When continuous jogging is deselected
- On reaching the first valid limit

Caution

Software limit switches and working area limitations are only activated after reference point approach.

- When a fault occurs

Note

While an axis is moving, a change of mode from JOG to AUT or MDA is disabled internally.
2.2.2 Special features of continuous jogging

Indexing axes
When an axis that is declared as an indexing axis is traversed in continuous JOG mode, it always traverses to indexing positions. For example, the axis traverses on to the next indexing position in the direction of travel even if the key is released in jog mode.

References: /FB/, T1, “Indexing Axes”

2.3 Incremental jogging (INC)

Programming increments
The traversing path to be traversed by the axis is defined by so-called increments (also termed “incremental dimensions”). Before the machine operator jogs the axis he must set the required increment. The setting is made on the machine control panel, for example. The IS “Machine function: INC1 to INCvar” (DB31, ... DBB5 ff) associated with the required increment is set by the PLC user program after appropriate logic operation.

Settable increments
The operator can set up to six different increment sizes. These are subdivided into:

- **five fixed increments** whose increment sizes are defined jointly for all axes with the general MD: JOG_INCR_SIZE_TAB (increment size INC/handwheel). The default settings are INC1, INC10, INC100, INC1000 and INC 10000.

- **and a variable increment** (INCvar). The increment setting for the variable increment also applies jointly to all axes and is made in SD: JOG_VAR_INCR_SIZE (size of the variable increment for INC/handwheel).

Increment weighting
Axial MD: JOG_INCR_WEIGHT (weighting of an increment of a machine axis for INC/handwheel) defines the path weighting of one JOG increment.

2.3.1 Distinction between jog mode and continuous mode

Selection
In incremental jogging, too, we distinguish between traversing in jog mode and continuous mode. The selection is made in the general MD: JOG_INC_MODE_LEVELTRIGGRD (INC and REF jog mode). Jog mode is the default setting.
Incremental jogging in jog mode

Function
If the traverse key for the required direction (e.g. +) is pressed, the axis begins to traverse the increment set. If the traverse key is released before the increment has been traversed the movement is interrupted and the axis stops. If the same key is pressed again, the axis moves the remaining distance until it is zero. As long as the remaining distance is greater than zero the movement can again be interrupted by releasing the traverse key. Pressing the key for the opposite direction has no effect until the increment has been completely traversed or the movement has been interrupted.

Aborting the traverse movement
If you do not want to traverse the whole increment, the traverse movement can be aborted with RESET or IS “Delete axial distance-to-go” (DB31, ... DBX2.2).

Incremental jogging in continuous mode

Function
The axis traverses the entire set increment when the traverse key is pressed (on the first rising edge). If the same traverse key is pressed again (second rising edge) before the axis has traversed the increment the traverse movement is interrupted; i.e. not completed.

Interrupting the traverse movement
As for continuous jogging.

Aborting the traverse movement
The traverse movement is stopped and aborted by the following operator action or monitoring functions:
- Same traverse key pressed again (second rising edge)
- Traverse key for the opposite direction pressed
- RESET
- Delete axial distance-to-go (PLC interface signal)
- On reaching the first valid limit

Caution
Software limit switches and working area limitations are only activated after reference point approach.

- on deselection or change of the current increment (e.g. change from INC100 to INC 10)
- on faults (e.g. on cancellation of the servo enable)
2.3 Incremental jogging (INC)

---

**Note**

While an axis is moving, a change of mode from JOG to AUT or MDA is disabled internally.

---

**Warning**

If “continuous” mode is selected, several axes can be started by pressing and releasing the relevant direction key. Any interlocks must be implemented via the PLC!

---

2.3.2 Special features of incremental jogging

**Indexing axes**

Regardless of the currently set incremental value, the axis declared as an indexing axis (MD: INDEX_AX_ASSIGN_POS_TAB) traverses to the next highest indexing position after the traverse key “+” is pressed. In a similar way, if the traverse key “−” is pressed it moves to the next lowest indexing position.

**References:** /FB/, T1, “Indexing axes”
2.4 Handwheel traversal in JOG

Selection
JOG mode must be active. The operator must also set the increment INC1, INC10, ... which applies when jogging with the handwheel. As with incremental jogging the required machine function must be set at the PLC interface accordingly.

Traversing
When the electronic handwheel is turned the associated machine axis is traversed either in the positive or negative direction depending on the direction of rotation.

Traversing path
The traversing path produced by rotation of the handwheel is dependent on the following factors:

- Number of handwheel pulses received at the interface
- Active increment (machine function INC1, INC10, INC100, ... INCvar)
- Handwheel pulse weighting with general MD: HANDWH_IMP_PER_LATCH (handwheel pulses per detent position)
- Evaluation of an increment with INE/handwheel (axis-specific MD: JOG_INCR_WEIGHT).

Travel command +/-
While the axis is moving the IS "Travel command+" or "Travel command-" (DB31, ... DBX64.7 or DBX64.6) is output depending on the direction of movement.

If the axis is already being moved using the direction keys, the handwheel cannot be used. Alarm 20051 "Jogging with the handwheel not possible" is output.

Handwheel connection
Two handwheels can be connected simultaneously. In this way, up to two axes can be traversed by handwheel simultaneously.

Exception: If several axes are assigned to one handwheel, more than two axes can be traversed with handwheels.

Handwheel assignment
A separate axis-specific VDI interface signal is used to make the assignment between a handwheel and a geometry or machine axis.

The axis to be moved as a result of rotating handwheel 1 or 2 can be set:

- Via the PLC user interface with IS "Activate handwheel" (DB31-48, DBX4.0 to DBX4.2) (with geometry axis: DB21, ... DBX12.0 – 12.2 ff)
- By menu-guided operation (MMC)

Operating the softkey Handwheel in the JOG mode basic menu displays the window "Handwheel". Here, every handwheel can be assigned an axis and the handwheel can be enabled or disabled.
The assignment is transferred to the PLC interface through the logic of the PLC user program. In this way, several axes can be assigned to one handwheel simultaneously.

**Function**

The electronic handwheels (accessories) can be used to simultaneously traverse selected axes manually. The weightings assigned to the divisions of the handwheel are defined by the increment size weighting. Where coordinate offset or rotation is selected, handwheel jogging can even be performed in the transformed workpiece coordinate system.

**Handwheel selection from MMC**

A separate user interface between the MMC and PLC is provided to allow activation of the handwheel from the operator panel. This interface that the basic PLC program supplies for handwheels 1 and 2 contains the following information:

- The axis numbers assigned to the handwheel is “Axis number handwheel n” (DB10, DBB100 ff)
- Additional information on machine or geometry axis is “Machine axis” (DB10, DBX100.7 ff)
- The channel number assigned to the handwheel if a geometry axis has been selected on handwheel selection is “Channel number geometry axis handwheel n” (DB10, DBX97 ff)
- Information that the handwheel is enabled or disabled is “Handwheel deselected” (DB10, DBX100.6 ff)

The IS “Activate handwheel” is either set to “0” (disable) or to “1” (enable) by the basic PLC program for the defined axis.

**Input frequency**

The handwheel connections can receive handwheel pulses with a maximum input frequency of 100 kHz.

**Velocity**

The axis velocity settings SD: JOG_SET VELO (JOG velocity for G94), MD: JOG_VELO (jogging axis velocity) and SD: JOG_ROT AX_SET VELO (JOG velocity for rotary axes) which are active in JOG are also used for jogging with the handwheel.

Because of the limited feedrate, the axis is not able to follow the handwheel turn synchronously, especially in the case of large pulse weighting, and therefore lags behind.

**Abortion of traversing movement**

The traversing movement is aborted as the result of a RESET or the IS “Axial deletion of distance-to-go” (DB31, ... DBX2.2). The setpoint/actual-value difference is deleted. STOP only interrupts the traversing movement. Any setpoint/actual-value difference is maintained. The distance-to-go is then traversed on START.
The operator can delimit the size (MD: HANDWH_GEOAX_MAX_INCR_SIZE).

The size of the selected increment for machine axes can be delimited with the axial machine data (MD: HANDW_MAX_INCR_SIZE).

A traversing movement defined by the handwheel for a geometry axis is defined by

- traversing path
- size of the variable increment (SD: JOG_VAR_INCR_SIZE)
- geometry axis allocation (MD: HANDWH_GEOAX_MAX_INCR_SIZE)

or for a machine axis by

- traversing path
- size of the variable increment (SD: JOG_VAR_INCR_SIZE)
- machine axis allocation (MD: HANDWH_MAX_INCR_SIZE)

Depending on the machine data $MN\_HANDWH\_REVERSE$, the behavior with a change of the traversing direction is as follows:

- If the handwheel is moved in the opposite direction, the resulting distance is computed and the calculated end point is approached as fast as possible: If this end point is located before the point where the moving axis can decelerate in the current movement direction, the unit is decelerated and the end point is approached by movement in the opposite direction. If this is not the case, the newly calculated end point is approached immediately.

- If the handwheel is moved in the opposite direction by at least the number of pulses indicated in the machine data, the axis is decelerated as fast as possible and all pulses received until the end of interpolation are ignored. That means, another movement takes place only after zero speed (setpoint side) of the axis (new function). This feature is available with SW 3.2 and higher.

The acceleration rate for handwheel traversal is determined by the acceleration characteristic programmed in MD: AX_JERK_DEFAULT (Initial setting of axial jerk limitation).

When axes are traversed in JOG mode, they can traverse only up to the first active limitation before the appropriate alarm is output. Depending on the machine data $MN\_HANDWH\_REVERSE$, the behavior is as follows (as long as the axis on the setpoint side has not yet reached the end point):

- The distance resulting from the handwheel pulses forms a fictitious end point which is used for the subsequent calculations: If this fictitious end point is positioned for example 10 mm behind the limitation, these 10 mm must be traversed in the opposite direction before the axis traverses again. If a movement in the opposite direction shall be performed immediately after a limitation, the fictions distance-to-go can be deleted via delete distance-to-go or deselection of the handwheel allocation.

- All handwheel pulses leading to an end point behind the limitation are ignored. Any movement of the handwheel in the opposite direction results immediately in a movement in the opposite direction, i.e. away from the limitation. This feature is available with Software Version 3.2 and higher.

The limitations are also active when jogging with the handwheel. For further information see Section 2.8.3.

In JOG mode, the operating characteristics of the axis/spindle are also dependent on the values set in setting data JOG\_REV\_IS\_ACTIVE (revolutional feedrate active for JOG).

- If this setting data is active, an axis/spindle is always moved with revolutional feedrate MD\_JOG\_REV\_VELO (revolutional feedrate with JOG) or MD\_JOG\_REV\_VELO\_RAPID (revolutional feedrate with JOG with rapid traverse overlay) depending on the master spindle.

- If the setting data is not active, the behavior of the axis/spindle depends on the setting data ASSIGN\_FEED\_PER\_REV\_SOURCE (revolutional feedrate for positioning axes/spindles)

- If the setting data is not active, the behavior of a geometry axis on which a frame with rotation is effective depends on the channel-specific setting data JOG\_FEED\_PER\_REV\_SOURCE. (In the operating mode JOG, revolutional feedrate for geometry axes on which a frame with rotation is effective).
2.5 Handwheel override in automatic mode

2.5.1 General functionality

**Function**

With this function it is possible to traverse jog axes or to change their velocities directly with the handwheel in Automatic mode (Automatic, MDA). The handwheel override is activated in the NC part program using the NC language elements FD (for path axes) and FDA (for positioning axes) and is **non modal**. With positioning axes, it is possible to activate the handwheel override modally using the traverse instruction POSA. When the programmed target position is reached, the handwheel override is deactivated again. Other axes can interpolate or traverse simultaneously in the same NC block.

The function for concurrent positioning axes can also be activated by the PLC user program.

**Distinction**

Depending on the programmed feedrate, a distinction is made between the following:

- **Path definition**
  - Axis feedrate = 0 (FDA = 0) and
  - **Velocity override**
  - Axis feedrate > 0 (FD or FDA > 0)

Table 2-1 shows which axis types can be influenced by the function “handwheel override in Automatic mode”.

<table>
<thead>
<tr>
<th>Axis type</th>
<th>Velocity override</th>
<th>Path definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Positioning axis</td>
<td>FDA[AXi] &gt; 0 ; axial</td>
<td>FDA[AXi] = 0</td>
</tr>
<tr>
<td>Concurrent positioning axis</td>
<td>Parameter “handwheel override active” = 1 and axis feedrate &gt; 0 from FC 15</td>
<td>Parameter “handwheel override active” = 1 and axis feedrate = 0 from FC 15</td>
</tr>
<tr>
<td>Path axis</td>
<td>FD &gt; 0 ; applies to path velocity</td>
<td>Not possible</td>
</tr>
</tbody>
</table>

**Path definition**

With an axis feedrate setting = 0 (e.g. when FDA[AXi] is programmed as 0), the traversing movement of the positioning axis towards the programmed target position is controlled entirely by the operator rotating the assigned handwheel.

The direction in which the handwheel is turned determines the direction in which the axis traverses. The programmed target position cannot be exceeded during handwheel override. The axis can also be moved in the direction opposite to that programmed, the movement in the opposite direction only being restricted by the axial position limits.
A block transition occurs

- When the axis has reached the programmed target position or
- the distance-to-go is deleted by the axial IS “Delete distance-to-go” (DB31, ... DBX2.2).

From this moment on, the path definition is deactivated and any further handwheel pulses have no effect.

After this, incrementally programmed positions refer to the point of interruption and not to the last programmed position.

**Velocity override**

With regard to the velocity override, a distinction is made between axis feed and path feed.

- **Override for the axis velocity** (FDA[AXi] > 0):
  The positioning axis is moved to the target position at the programmed axial feedrate. With the assigned handwheel it is possible to increase the axis velocity or to reduce it to a minimum of zero depending on the direction in which the handwheel is turned. The resulting axis feedrate is limited by the maximum velocity. The axis cannot be traversed in the direction away from the target position. As soon as the axis has reached the programmed target position, a block transition occurs.
  In this way, the velocity override is automatically deactivated again and any further handwheel pulses have no effect.
  This also applies to concurrent positioning axes, but the target position and the velocity are set by the PLC.

- **Override for the path velocity** (FD > 0):
  The path axes programmed in the NC block move to the target position at the programmed path feedrate. If the velocity override is active, the programmed path velocity is overridden by the velocity generated with the handwheel of the 1st geometry axis. As soon as the programmed target position is reached, a block transition occurs.
  Depending on the direction in which the handwheel is turned, the path velocity is increased or reduced to a minimum of zero. It is not possible to reverse the direction of the movement with the handwheel override.

**Example of application**

The “Handwheel override in AUTOMATIC mode” function is frequently used on grinding machines. For example, the operator can position the reciprocated grinding wheel on the workpiece using the handwheel (path definition). After scratching, the transverse movement is terminated and the block transition is initiated (by activating “Delete distance-to-go”).

**Requirements**

In order to activate “Handwheel override in AUTOMATIC mode” the following conditions must have been met

- A handwheel must be assigned to the axis in question.
- Pulse weighting is programmed for the assigned handwheel.
Handwheel assignment

The connected handwheels are assigned to the axes analogously to the procedure described in Section 2.4, i.e. via the PLC user interface with IS “Activate handwheel” (DB31, ... DBX4.0 to DBX4.2) or by means of menu-assisted operator inputs.

If an axis is programmed for the handwheel override and no handwheel is assigned to it, the following cases are possible:

- With velocity override
  The axes are traversed at the programmed velocity. A self-acknowledging alarm is output (without response).

- With path definition
  No traverse movement is performed, because the velocity is zero. A self-acknowledging alarm is output (without response).

Note

When the velocity override is applied to path axes, only the handwheel of the 1st geometry axis acts on the path velocity.

Handwheel weighting

The traversing path of the axis that is generated by advancing the handwheel by one detent position is dependent on several factors (see Section 2.4).

- The selected increment size (general MD: JOG_INCR_SIZE_TAB[5] or axial SD: JOG_VAR_INCR_SIZE)
- The weighting of an increment (axial MD: JOG_INCR_WEIGHT)
- Number of handwheel pulses per detent position (general MD: HANDWH_IMP_PER_LATCH)

For example, the axis traverses by 0.001 mm per handwheel detent position if machine function INC1 and the standard setting of the above machine data are selected.

With the velocity override, the velocity results from the path covered using the handwheel within a period of time.

Example

Assumptions:
The operator turns the handwheel at 100 pulses/second.
The selected machine function is INC100.
Machine data specified above for handwheel weighting with default setting
⇒ Handwheel traversing path per second: 10 mm
⇒ Velocity override: 0.6 m/min

PLC interface signals

As soon as the handwheel override takes effect, the following interface signals to the PLC are set to “1”:

- With positioning axes:
  IS “Handwheel override active” (DB31, ... DBX62.1)

- With concurrent positioning axes:
  IS “Handwheel override active” (DB31, ... DBX62.1)

- With path axes:
  IS “Handwheel override active” (DB21, ... DBX33.3)
With the path definition, the IS “Traverse commands +/-” (DB31, ... DBX64.6 and 64.7) are output to the PLC depending on the direction of travel.

Limitations

The axial limitations (SW limit switches, HW limit switches, working area limitations) are effective in conjunction with handwheel override. With the path definition, the axis can be traversed with the handwheel in the programmed direction of travel only as far as the programmed target position.

The resulting velocity is limited by the axial MD: MAX_AX_VELO (maximum axis velocity).

NC STOP/override = 0

If the feedrate override is set to 0% or an NC STOP is initiated while the handwheel override is active, the following applies:

- With path definition
  The handwheel pulses arriving in the meantime are summated and stored.
  On NC start or feedrate override > 0%, the stored handwheel pulses are activated (i.e. traversed).
  However, if the handwheel is deactivated first (IS “Activate handwheel n” DB21, ... DBX12/16/20), the stored handwheel pulses are deleted.

- With velocity specification
  The handwheel pulses arriving in the meantime are not summated and are not active.

2.5.2 Programming and activation of handwheel override

General notes

When the handwheel override is programmed with the NC language elements FD (for path axes) and FDA (for positioning axes), the following points must be observed:

- FDA and FD are nonmodal.
  There is an exception with respect to positioning axes: If the traverse instruction POSA is programmed, the handwheel override can be active beyond block boundaries because the block transition is not affected by the positioning axis.

- When the handwheel override is activated with FDA or FD, a target position must be programmed in the NC block for the positioning axis or for a path axis. When the programmed target position is reached, the handwheel override is deactivated again.

- It is not possible to program FDA and FD or FA and F in the same NC block.

- The positioning axis must not be an indexing axis.
**Positioning axis**

Syntax for handwheel override: \( \text{FDA}[AXi] = \text{[feed value]} \)

Example 1

Activate velocity override

\[ \text{N10 POS[U]=10 FDA[U]=100 POSA[V]=20 FDA[V]=150} \ldots \]

\( \text{POS[U]=10} \) Target position of positioning axis U
\( \text{FDA[U]=100} \) Activate velocity override for positioning axis U; the axis velocity of U is 100 mm/min
\( \text{POSA[V]=20} \) Target position of positioning axis V
\( \text{FDA[V]=150} \) Activate velocity override for positioning axis V; the axis velocity of V is 150 mm/min

Example 2

Activate path definition and velocity override in the same NC block

\[ \text{N20 POS[U]=100 FDA[U]=0 POS[V]=200 FDA[V]=150} \ldots \]

\( \text{POS[U]=100} \) Target position of positioning axis U
\( \text{FDA[U]=0} \) Activate path definition for positioning axis U;
\( \text{POS[V]=200} \) Target position of positioning axis V
\( \text{FDA[V]=150} \) Activate velocity override for positioning axis V; the axis velocity of V is 150 mm/min

**Path axis**

Syntax for handwheel override: \( \text{FD} = \text{[feed value]} \)

To program "handwheel override in Automatic mode" for path axes, the following conditions must be fulfilled:

- Active movement commands from group 1: G01, G02, G03, CIP
- Exact stop active (G60)
- Linear feed in mm/min or inch/min active (G94)

These conditions are checked by the control and an alarm is output if any of them is not met.

Example 3

Activate velocity override

\[ \text{N10 G01 X10 Y100 Z200 FD=1500} \ldots \]

\( \text{X10 Y100 Z200} \) Target position of path axes X, Y and Z
\( \text{FD=1500} \) Activate velocity override for path axes; the path velocity is 1500 mm/min
2.5 Handwheel override in automatic mode

Concurrent positioning axis

The handwheel override for concurrent positioning axes is activated from the PLC via FC15. The appropriate parameter “Handwheel override ON” is set for this purpose.

If the parameter velocity (F_value) is assigned the value 0, the activated handwheel override acts as a path definition (i.e. the feedrate is not derived from the axial MD: POS_AX VELO (initial setting for positioning axis velocity)).

References: /FB/, P2, “Positioning axes”
/FB/, P3, “Basic PLC program”

2.5.3 Special features of handwheel override in automatic mode

Velocity display

The velocity display for handwheel override shows the following values:
- Set velocity: programmed velocity
- Actual velocity: Resultant velocity including handwheel override

Effect on transverse axes

If the axis is defined as a transverse axis and DIAMON is active, the handwheel pulses are interpreted as diameter values and traversed as such while handwheel override is active.

Dry run feedrate

If the dry run is active (IS “Activate dry run feedrate” (DB21, ... DBX0.6=1)), the dry run feedrate always applies (SD: DRY_RUN_FEED).
In this way, the axis is traversed at dry run feedrate without the handwheel influencing the programmed target position despite the active handwheel override with path definition (FDA[AXi]=0) (i.e. the path definition is not active).

DRF active

When “Handwheel override in automatic mode” is activated it is important to check whether the function DRF is active (IS “Activate DRF” (DB21, ... DBX0.3=1)). In this case, the handwheel pulses would also cause a DRF offset of the axis. The operator must therefore deactivate DRF first (see Section 2.9).

Feedrate override

The feedrate override does not affect the velocity of the movements produced by the handwheel (exception: 0%). It only acts on the programmed feedrate.
With path definition and rapid jogging with handwheel, the axis might not follow the rotation of the handwheel synchronously (especially with a large handwheel pulse weighting), so that the axis lags.
2.6 Third handwheel via actual-value input (840D, 810D)

Function

To date:
It is possible to connect two handwheels to the peripheral interface (X121, 37-pin) on the NCU module using the cable distributor, etc.

840D with SW 4.1 and higher, 810D with SW 2.1 and higher:
It is now possible to connect a third handwheel via a 611D actual-value input that can be selected in a machine data.
A third handwheel could be used, for example, as a contour handwheel.

Comparison of the 3 handwheels
All three handwheels are identical in terms of operating procedures and functionality.
The third handwheel differs from the others only in terms of its connection method.

Connecting the handwheel to the actual-value input
The signals from the handwheel (track A, *A, B, *B, 5V and 0V) must be wired to the actual-value input as follows:

<table>
<thead>
<tr>
<th>Pin 3</th>
<th>A</th>
<th>Yellow</th>
<th>(colors are only valid if the recommended cable is used)</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>*A</td>
<td>Green</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>B</td>
<td>Black</td>
<td></td>
</tr>
<tr>
<td>7</td>
<td>*B</td>
<td>Brown</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>+5V</td>
<td>White-black</td>
<td></td>
</tr>
<tr>
<td>14</td>
<td>+5V</td>
<td>White-red</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>0V</td>
<td>White-yellow</td>
<td></td>
</tr>
<tr>
<td>16</td>
<td>0V</td>
<td>White-blue</td>
<td></td>
</tr>
</tbody>
</table>

Handwheel with tracks A, *A, B, *B, +5V, 0V

Actual-value input 25-pin female connector

Note: Put cable shield on both sides

Fig. 2-2 Connecting a handwheel to an actual-value input

Recommendation:

- Use the “Actual-value cable for encoder with voltage signals” (6FX2002–2CG00– ...)
- Separate the cable at the circular connector, remove outer shield and connect to earth potential.
- Apply handwheel signals as shown in Fig. 2-2
### Activation, machine data and interface signals

The following machine data and interface signals are required to activate the third handwheel:

- **Machine data**
  - MD 11340: $MN_ENC_HANDWHEEL_SEGMENT_NR
  - MD 11342: $MN_ENC_HANDWHEEL_MODULE_NR
  - MD 11344: $MN_ENC_HANDWHEEL_INPUT_NR

- **Interface signals**
  - IS “Channel number for handwheel 3” (DB10, DBX99.0, 99.1, 99.2)
  - IS “Axis number for handwheel 3” (DB10, DBX102.0 to 2.4)
  - IS “Define handwheel 3 as contour handwheel” (DB10, DBX102.5)
  - IS “Handwheel 3 selected” (DB10, DBX102.6)
  - IS “Define axis” (DB10, DBX102.7)
  - IS “Activate handwheel 3” (DB21, ... , DBX12.2, 16.2, 20.2)
  - IS “Handwheel 3 active” (DB21, ... , DBX16.2, 20.2)
  - IS “Activate handwheel 3” (DB31, ... , DBX40.2)
  - IS “Handwheel 3 active” (DB31, ... , DBX44.2)

### Supplementary conditions

- The alarm “Handwheel %1 configuration incorrect or inactive” is output to indicate incorrect parameterization of the measuring circuit connection or missing hardware components during POWER ON.
- In contrast to actual-value encoders, no encoder monitors are provided when handwheels are connected. The handwheel pulses disappear in the event of a hardware defect or cable break.
- There is no interlocking to prevent duplicate assignment of an actual-value input, i.e. the input can theoretically be assigned to an actual-value encoder for sensing position or speed or to the “third” handwheel. In this case, “handwheel” pulses are evaluated according to the number of encoder pulses per revolution (coarse increments).
- The third handwheel cannot be operated until the SIMODRIVE 611D bus has powered up.

2.7 Contour handwheel / path definition by handwheel (840D, 810D)

Function
When the function is active, the feedrate of the path and synchronous axes can be controlled by a handwheel in AUTOMATIC and MDA modes.

Operating characteristics of function
The following operating characteristics in conjunction with the contour handwheel can be set in MD $MN_HANDWH_TRUE_DISTANCE:

- Path definition:
  Limitation of the axis velocity to the maximum permissible value causes the axes to overtravel. The path defined by the handwheel is traversed, no pulses are lost.

- Velocity specification:
  The handwheel specifies only the velocity at which the axes must be traversed. As soon as the handwheel stops, the axes also reach a standstill. The movement is decelerated immediately if no pulses are received from the handwheel within one IPO cycle. As a result, there is no axis overtravel. The handwheel pulses do not define the traversing path.

Feedrate
The feedrate in mm/min is dependent on:

- the number of pulses of the selected handwheel within one time period
- the handwheel pulse evaluation method set in MD $MN_HANDWH_IMP_PER_LATCH
- the activated increment (INC1, 10, 100, ...)
- the path weighting of an increment ($MA_JOG_INCR_WEIGHT of first available geometry axis)

The feedrate does not depend on:

- the programmed feed mode (mm/min, mm/rev.)
- the programmed feedrate (resultant velocity might even be higher)
- the rapid traverse rate with respect to G0 blocks
- the override (a setting of 0% is effective, i.e. zero speed)

Travel direction
The travel direction is dependent on the rotational direction:

- Clockwise rotation: Axis traverses in the programmed direction
  If the block change criterion (IPO end) is reached, then the next block is inserted (identical response to G60).

- Anti-clockwise rotation: Axis traverses in the programmed direction
  In this case, the axis can traverse only up to the start of the next block. The pulses are not picked up if the handwheel continues to rotate.
2.7 Contour handwheel / path definition by handwheel (840D, 810D)

**Activation of function**

The function can be activated either by interface signals or by the NC program.

- Activation via interface signal “Activate handwheel x as contour handwheel”
  The function is activated/deactivated via the following interface signal:
  IS “Activate handwheel x as contour handwheel” (DB21, ... DBX30.0, 30.1, 30.2)

- Activation via NC program
  The contour handwheel can be activated non-modally with FD=0 in the NC program, i.e. velocity F from the block in front of the handwheel applies automatically in the following block **without** having to be programmed again.

**Note**

If the preceding NC blocks do not contain a feedrate, then an appropriate alarm is output.
FD and F in one NC block are mutually exclusive (e.g. generate an alarm).

**Simulation of contour handwheel**

The contour handwheel can be simulated when it is activated. Once it has been activated via an interface signal, the feedrate is no longer determined by the handwheel, but the programmed feedrate value is applied instead. The direction of travel is specified via an interface signal.

IS “Simulation of contour handwheel” (DB21, ... DBX30.3)

<table>
<thead>
<tr>
<th>If</th>
<th>then</th>
</tr>
</thead>
<tbody>
<tr>
<td>the simulation function is deselected,</td>
<td>the current movement is decelerated along a braking ramp</td>
</tr>
<tr>
<td>the direction of travel is reversed,</td>
<td></td>
</tr>
</tbody>
</table>

**Note:**

The override works as for execution of the NC program.
Supplementary conditions

- **Preconditions**
  Fixed feedrate, dry run feedrate, thread cutting or tapping must not be selected.

- **Limit values**
  The limit values for acceleration and velocity defined in machine data for the relevant axes are applied.

- ** Interruption of traversing movement**
  The function remains selected after an NC STOP, but the handwheel pulses are no longer summated and are ineffective (on the condition, however, that MD $MC_HANDWH_CHAN_STOP_COND bit 2 = 1).

- **DRF**
  If selected, a DRF function has an additional path override effect.

- **Channel-specific deletion of distance-to-go**
  This causes the movement initiated by the handwheel to be aborted, the axes are decelerated and the program restarted at the next NC block. The contour handwheel then becomes operative again.

### Machine data

<table>
<thead>
<tr>
<th>MD number</th>
<th>$MN_HANDWH_TRUE_DISTANCE</th>
<th>Path definition or velocity specification by handwheel</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default value: 1</td>
<td>Min. input limit: 0</td>
<td>Max. input limit: 3</td>
</tr>
<tr>
<td>Changes effective after Power On</td>
<td>Protection level: 7/2</td>
<td>Unit: –</td>
</tr>
<tr>
<td>Data type: BYTE</td>
<td>Applies from SW version: 840D SW4.1</td>
<td>810D SW2.1</td>
</tr>
</tbody>
</table>

**Significance:**
- Setting the operating characteristics for traversal with handwheel, contour handwheel or FDA=0:
  - **Value = 1:** The handwheel pulses define the traversing path. No pulses are lost. Axis overtravel occurs as a result of limiting the velocity to its maximum permissible value.
  - **Value = 0:** The handwheel pulses specify the axis travel velocity. As soon as the handwheel stops, the axes also reach a standstill. The movement is decelerated immediately if no pulses are received from the handwheel within one IPO cycle. As a result, the axes do not overtravel. The handwheel pulses do not define the traversing path.
  - **Value = 2** The inputs from the handwheel are velocity inputs. As soon as the handwheel stops, the axes also reach a standstill. The movement is decelerated immediately, value = 0, but not via the shortest possible path, but to the next possible path on an imaginary grid. This grid corresponds in each case to a distance travelled by the selected axis per handwheel detent position (see $MA\_JOG\_INCR\_WEIGHT and $MN\_JOG\_INCR\_SIZE\_TAB, $MC\_HANDWH\_GEOAX\_MAX\_INCR\_SIZE, $MA\_HANDWH\_MAX\_INCR\_SIZE). The start point of the traversing motion is assumed to be the grid zero point.
  - **Value = 3** The inputs from the handwheel are path inputs. If the axis needs to be decelerated prematurely owing to the settings in other MD ($MN\_HANDWH\_REVERSE = 0, $MC\_HANDWH\_CHAN\_STOP\_COND, $MA\_HANDWH\_STOP\_COND), then, unlike value = 1, the axis is not decelerated via the shortest possible path, but to the next possible point on an imaginary grid.
### Interface signals

<table>
<thead>
<tr>
<th>DB 21, 22, ...</th>
<th>Activate handwheel 1 as contour handwheel</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBX30.0</td>
<td>Activate handwheel 2 as contour handwheel</td>
</tr>
<tr>

<td>Activate handwheel 3 as contour handwheel</td>
</tr>
<tr>
<td>DBX30.2</td>
<td>Signal(s) to channel (PLC –– NCK)</td>
</tr>
<tr>
<td>Data block</td>
<td></td>
</tr>
</tbody>
</table>

**Edge evaluation:** no  
**Signal(s) updated:** cyclically  
**Signal(s) valid from SW vers.:**  
- 840D SW4.1, 810D SW2.1

**Description**  
These signals allow one of the three handwheels to be selected/deselected as the contour handwheel.

- **Signal = 1**  
  Handwheel x is selected as the contour handwheel

- **Signal = 0**  
  Handwheel x is deselected as the contour handwheel

The contour handwheel can be selected/deselected in the middle of a block. When the handwheel is activated, the axis movement is first decelerated and then traversed as determined by the handwheel. When the handwheel is deactivated, the movement is first decelerated before execution of the NC program continues. If the NC program must not continue until after a new NC-START, then deactivation of the contour handwheel must be linked to an NC-STOP in the PLC user program.

**Special cases, errors, ......**  
The signal setting remains valid after an NC-RESET.

**Related to ....**  
IS "Handwheel x active as contour handwheel" (DB21, 22, ..., DBX37.0, 37.1, 37.2)
### 2.7 Contour handwheel / path definition by handwheel (840D, 810D)

#### DB 21, 22, ...

<table>
<thead>
<tr>
<th>DB21, 22, ...</th>
<th>Simulation of contour handwheel ON</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBX30.3</td>
<td>Negative direction simulation of contour handwheel</td>
</tr>
<tr>
<td></td>
<td>Signal(s) to channel (PLC (\rightarrow) NCK)</td>
</tr>
</tbody>
</table>

**Edge evaluation:** no  
**Signal(s) updated:** cyclically  
**Signal(s) valid from SW vers.:**  
840D SW4.1, 810D SW2.1

**Description:**  
To activate/deactivate simulation of the contour handwheel and to set the traversing direction, these signals must be set as follows:

<table>
<thead>
<tr>
<th>Bit 3</th>
<th>Bit 4</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>Simulation OFF</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>Simulation OFF</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>Simulation ON, direction as programmed</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Simulation ON, opposite direction to programmed direction</td>
</tr>
</tbody>
</table>

During simulation, the feedrate is not determined by the contour handwheel, but the axis is traversed along the contour at the programmed feedrate.

If the function is deselected, the current axis movement is decelerated along a braking ramp.

When the traversing direction is reversed, the current axis movement is decelerated along a braking ramp and the axis then traversed in the opposite direction.

**Special cases, errors, ......**  
The simulation function is available only in AUTOMATIC mode and can only be activated if the contour handwheel is already active.

840D SW4.1, 810D SW2.1

**Description:**  
These signals indicate which handwheel is defined as the contour handwheel via the MMC.

Signal = 1  
Handwheel x is defined as the contour handwheel via the MMC

Signal = 0  
Handwheel x is not defined as the contour handwheel

To ensure that the handwheel defined via the MMC can operate as the contour handwheel, the appropriate signal must be gated with IS "Activate handwheel x as contour handwheel" (DB21, 22, ..., DBX30.0, 30.1, 30.2).

**Special cases, errors, ......**  
Depending on the setting of parameter HWheelMMC in FB1 of the basic PLC program, these signals are supplied by the basic program or must be supplied by the PLC user program.

**Related to ......**  
IS "Activate handwheel x as contour handwheel" (DB21, 22, ..., DBX30.0, 30.1, 30.2)  
FB1 parameter HWheelMMC
2.8 Special features of JOG mode

2.8.1 Geometry axes in JOG mode

Coordinate systems in JOG mode
In JOG mode the operator can also jog the axes declared as geometry axes in the workpiece coordinate system. Any coordinate offsets or rotations that have been selected remain active.

The special features of jogging geometry axes are described below.
The geometry axes are traversed in the coordinate system that was last activated.

Simultaneous jogging
Only one geometry axis can be jogged continuously or incrementally using the traverse keys. Where an attempt is made to jog more than one geometry axis, alarm 20062 “Axis already active” is output. If the axis is not defined as a geometry axis, alarm 20060 “Axis cannot be traversed as geometry axis” is output. However, 3 geometry axes can be jogged simultaneously with handwheels 1, 2 and 3.

PLC interface
The geometry axes have their own PLC interface (DB21, ... DBB12-23 and DBB40-56) which contains the same signals as the axis-specific PLC interface.

Feedrate/rapid traverse override
The channel-specific feedrate override switch and rapid traverse override switch are active for jogging geometry axes.

Alarms
Alarm 20062 “Axis already active” is triggered when a geometry axis is being jogged under the following conditions:
- The axis is already being traversed in JOG mode via the axial PLC interface.
- A frame for a rotated coordinate system is already active and another geometry axis in this coordinate system is traversed in JOG mode with the traverse keys.

If the axis has not been defined as a geometry axis, alarm 20060 is triggered if an attempt is made to traverse it as a geometry axis in JOG mode.

Use
Jogging movements for which transformations and frames have to be active.
2.8.2 Special features of spindle jogging

**Spindle traversal in JOG mode**
Spindles can also be traversed manually in JOG mode. Essentially the same conditions apply as for manual traverse of axes. Spindles can be traversed in JOG mode using the traverse keys continuously or incrementally, in continuous-trigger or momentary-trigger mode, or with the handwheel. The function is selected and activated via the axis/spindle-specific PLC interface in the same way as for the machine axes. The axis-specific machine axes also apply to the spindles.

**Spindle mode**
The spindle can be jogged in positioning mode (spindle is in position control) or in open-loop control mode.

**JOG speed**
The speed used for jogging spindles can be defined as follows:

- With the general SD: JOG_SPIND_SET VELO (JOG speed for spindle) which is activated for all spindles jointly
- Or with machine data JOG VELO (JOG axis velocity). However, this MD only has an effect if SD: JOG_SET VELO (JOG velocity for G94) = 0.

The maximum speed for the active gear stage also applies when spindles are traversed in JOG mode.

**References:** /FB/, S1, “Spindles”

**Speed override**
The spindle speed override switch can be used to modify the speed of spindles traversed in JOG mode.

**JOG acceleration**
Because a spindle often uses many gear stages in speed control and position control mode, the acceleration programmed for the current gear stage is always applied in spindle JOG mode.

**References:** /FB/, S1, “Spindles”
Plc Interface Signals

When spindles are traversed manually, the PLC interface signals between the NCK and PLC have the same effect as for machine axes. IS “Position reached with exact stop fine or coarse” (DB31, ... DBX60.7 or DBX60.6) is only set if the spindle is in position control mode. For purely spindle-specific interface signals the following should be noted when traversing spindles in JOG:

- The following PLC interface signals to the spindle have no effect:
  - IS “Invert M3/M4” (DB31, ... DBX17.6)
  - IS “Set direction of rotation ccw” or “Set direction of rotation cw” (DB31, ... DBX18.7 or DBX18.6)
  - IS “Oscillation speed” (DB31, ... DBX18.5)
  - IS “Spindle RESET” (DB31, ... DBX16.7)

- The following PLC interface signals from the spindle are not set:
  - IS “Actual speed cw” (DB31, ... DBX83.7)
  - IS “Spindle in set range” (DB31, ... DBX83.5)

2.8.3 Monitoring functions

Limitations

The following limitations are active in JOG mode:

- Working area limitation (axis must be referenced)
- Software limit switches 1 and 2 (axis must be referenced)
- Hardware limit switches

The control ensures that the traversing movement is aborted as soon as the first valid limitation has been reached. Velocity control ensures that deceleration is initiated early enough for the axis to stop exactly at the limitation position (e.g. software limit switch). Only when the hardware limit switch is triggered does the axis stop abruptly with “Rapid stop”.

Alarms are triggered when the various limitations are reached (alarms 16016, 16017, 16020, 16021). The control automatically prevents further movement in this direction. The traverse keys and the handwheel have no effect in this direction.

Important

The software limit switches and working area limitations are only active if the axis is first referenced.

For further information on working area limitations and hardware and software limit switches see:

Axis retraction

The axis can be retracted from a limitation position by moving it in the opposite direction.

Machine manufacturer

The function for retracting an axis that has reached the limitation position depends on the machine-tool manufacturer. Please refer to the machine-tool manufacturer’s documentation!

Maximum velocity and acceleration

The velocity and acceleration values applied in JOG mode are programmed for specific axes via machine data by the start-up engineer. The control limits the value for the values valid for the axes to the maximum velocity and acceleration specifications.

2.8.4 Miscellaneous

Switching modes from JOG—AUT or from JOG—MDA

It is possible to switch operating modes from JOG to AUT or MDA only if all axes in the channel have reached “Exact stop coarse”.

References: /FB/, K1, “Mode Group, Channels, Program Operation Mode”

Rotational feedrate active in JOG

In JOG mode, it is also possible to traverse an axis at a rotational feedrate (analogous to G95) referred to the current speed of the master spindle. The function is activated with SD: JOG_REV_IS_ACTIVE (JOG in rotational feedrate).

The feedrate value (in mm/rev) used can be defined as follows:

- With general SD: JOG_REV_SET_VELO (JOG speed for G95) if this is not equal to 0.
- If the value 0 is set in SD: JOG_REV_SET_VELO, then the rotational feedrate is determined by axial machine data JOG_REV_VELO (rotational feedrate for JOG) or, in the case of rapid traverse override, by JOG_REV_VELO_RAPID.

If a master spindle has not been defined and the axis is to be traversed in JOG at rotational feedrate, alarm 20055 and for geometry axes alarm 20065 is output.
Transverse axes

If a geometry axis is defined as a transverse axis and radius programming is selected (MD: DIAMETER_AX_DEF (geometry axes with transverse axis function)), the following must be noted when traversing in JOG:

- Continuous jogging:
  There are no differences when a transverse axis is traversed in continuous mode.

- Incremental jogging:
  Only half the distance of the selected increment size is traversed. For example, with INC10 the axis only traverses 5 increments when the traverse key is pressed.

- Jogging with the handwheel
  As for incremental jogging, only half the path is traversed per handwheel pulse.

References: /FB/, P1, “Transverse Axes”
2.9 DRF

Function DRF

With the function DRF (Differential Resolver Function) an additional incremental zero offset can be activated with the electronic handwheel in automatic mode during machining.

The same conditions apply to the handwheel assignment, pulse weighting, etc., as for manual traverse with the handwheel in JOG mode (see Section 2.4). In addition, the velocity generated by the handwheel in DRF can be reduced from the JOG velocity with the axial MD: HAND_VELO_OVERLAY_FACTOR (ratio of JOG velocity to handwheel velocity).

DRF offset

The DRF offset is an axis zero offset that is generated by means of DRF (i.e. traversing movement with handwheel in automatic mode). The DRF offset is active in the basic coordinate system.

Caution!

Zero offset with DRF is always active; i.e. for all modes and after RESET. It can, however, be suppressed non-modally in the part program.

References: /PA1/, Programming Guide Fundamentals

Uses

DRF is used for the following applications:

→ Compensating for tool wear within an NC block. Where NC blocks have a long machining time it might be necessary to compensate for tool wear manually within the NC block (e.g. large surface milling machines).

→ Highly precise compensation during grinding

→ Very simple temperature compensation

→ Offsets that are not included in the actual-value display

DRF active

DRF must be active to allow the DRF offset to be modified through traversal with the handwheel. The following conditions must be fulfilled:

• AUTOMATIC mode is selected (channel in RESET/interrupted/active)

• and IS “Activate DRF” (DB21, ... DBX0.3) = 1

DRF offset can be switched off for specific channels by the operator with the program control function. This is reported by the MMC with IS “DRF selected” (DB21, ... DBX24.3) to the PLC. The PLC program (basic PLC program or user program) transfers this interface signal as IS “Activate DRF” after logic combination.
Control of DRF offset

The DRF offset can be modified, deleted or read in the following ways (see Fig. 2-4):

- By the operator by jogging with the handwheel
- By the NC part program (in high-level language)
  - Reading the DRF offset (axis-specific)
  - Deleting the DRF offset for all axes in a channel (command “DRFOF”)

References: /PA1/, Programming Guide Fundamentals

- From PLC user program
  - Reading the DRF offset (axis-specific)

References: /FB/, P3,

“Basic PLC Program”

- From the MMC by the operator
  - Reading the DRF offset (axis-specific)

Fig. 2-4  Control of DRF offset
2.9 DRF

---

**Note**

If DRF offset is cleared the axis is not traversed!

---

**Power On**

The DRF offset is deleted by a Power On.

**Reference point approach**

If an axis with a DRF offset is referenced, the offset is deleted during phase 1 of the referencing operation!

It is not possible to specify a DRF offset with the handwheel while an axis is being referenced (e.g. with G74). Alarm 20053 “DRF not possible” is triggered.

**Display**

The axis position display (ACTUAL POSITION) does not change while an axis is being traversed with the handwheel in DRF. The current DRF offset can be displayed in the DRF window.
2.10 Installation and start-up

Note
Before installation can begin several conditions must be fulfilled. For procedure please see:

References: /IAD/, “Installation and Start-up Guide”
/IAF/, “Installation and Start-up Guide”

Machine/setting data
The machine and/or geometry axes can be traversed manually only if specific machine/setting data have been preset. The machine and setting data that apply specifically to manual traverse are listed below. A description of these data together with their default settings is given in Section 4.

**JOG continuously in jog mode**
- General SD: JOG_CONT_MODE_LEVELTRIGGRD (JOG continuously in jog mode)

**INC and REF in jog mode**
- General MD: JOG_INC_MODE_LEVELTRIGGRD (INC and REF in jog mode)

**Velocity**
- Axial MD: JOG_VELO (JOG axis velocity)
- Axial MD: JOG_VELO_RAPID (JOG rapid traverse)
- General SD: JOG_SET_VELO (JOG velocity for G94)
- General SD: JOG_ROT_AX_SET_VELO (JOG velocity for rotary axes)

**Revolutional feedrate**
- General SD: JOG_REV_IS_ACTIVE (revolutional feedrate active in JOG)
- Axial MD: JOG_REV_VELO (revolutional feedrate for JOG)
- Axial MD: JOG_REV_VELO_RAPID (revolutional feedrate for JOG with rapid traverse override)
- General SD: JOG_REV_SET_VELO (JOG speed for G95)

**Acceleration**
- Axial MD: AX_JERK_DEFAULT (initial setting for axial jerk limitation)
2.10 Installation and start-up

- **Incremental/Handwheel**
  - Axial MD: JOG_INCR_WEIGHT (weighting of an increment for INC/handwheel)
  - General SD: JOG_VAR_INCR_SIZE (size of a variable increment for INC/handwheel)
  - Axial MD: HANDWH_VELO_OVERLAY_FACTOR (ratio JOG velocity to handwheel velocity (DRF))
  - General MD: JOG_INCR_SIZE_TAB [n] (increment size for INC/handwheel)
  - General MD: HANDWH_IMP_PER_LATCH [n] (handwheel pulses per detent position [handwheel number])

- **Spindle**
  - General SD: JOG_SPIND_SET_VELO (JOG speed for spindle)
Supplementary Conditions

Availability of function
“Handwheel override in automatic mode”

The function is available on

- SINUMERIK FM-NC with NCU 570, with SW 2 and higher
- SINUMERIK 840D with NCU 571/572/573 with SW 2 and higher

SINUMERIK 840Di handwheels

Two handwheels can be connected to the SINUMERIK 840Di via the MCI Board Extension module on the SINUMERIK 840Di. The handwheels are connected via the 25-pin cable distributor interface (X121) on the MCI Board Extension module.

Data Descriptions (MD, SD)

4.1 General machine data

<table>
<thead>

</tr>
</tbody>
</table>

Significance:

1: Jog mode for JOG-INC and reference point approach
   - JOG-INC: When the traverse key is pressed in the required direction (e.g. +) the axis begins to traverse the set increment. If the key is released before the increment has been completely traversed, the movement is interrupted and the axis stops. If the same key is pressed again, the axis completes the remaining distance-to-go until it is 0.
   - Continuous mode for JOG-INC and reference point approach
     - JOG-INC: When the traverse key is pressed (first rising edge) the axis traverses the whole set increment. If the same key is pressed again (second rising edge) before the axis has completed traversing the increment, the movement is aborted, i.e. not completed.

The differences in axis traversing characteristics between the jog and continuous modes in JOG-INC are described in detail in Section 2.3.

For travel behavior in reference point approach see

Manual Travel and Handwheel Travel (H1)
### 20624 $MC\_HANDWH\_CHAN\_STOP\_COND$

**Definition of operating characteristics in jogging with handwheel**

<table>
<thead>
<tr>
<th>Default value: 0x3FF, 0x3FF, 0x3FF, ...</th>
<th>Min. input limit: 0</th>
<th>Max. input limit: 0xFFF</th>
<th>Changes effective after Power On</th>
<th>Protection level: 2/7</th>
<th>Unit: –</th>
<th>Data type: DWORD</th>
<th>Applies from SW version: 3.2</th>
</tr>
</thead>
</table>

**Significance:**
- **Bit==0** Interruption or collection of the distances preset via the handwheel
- **Bit==1** Abort of the traversing movement or no collection

**Bit allocation**
- **Bit 0:** Mode group stop
- **Bit 1:** Mode group stop axes plus spindle
- **Bit 2:** NC stop
- **Bit 3:** NC stop axes plus spindles
- **Bit 4:** Feedrate disable
- **Bit 5:** Feedrate override
- **Bit 6:** Rapid traverse override
- **Bit 7:** Feed stop geometry axis
  - **Bit 7==0:** Interruption/collection
  - **Bit 7==1:** Abort traversing movement/no collection

**Setting for geometry axes**
- **Bit 8 = 0** For JOG with handwheel, the maximum possible velocity corresponds to the feedrate set in MD 32020: JOG_AX_VELO for the appropriate machine axis/axes.
- **Bit 8 = 1** For JOG with handwheel, the maximum possible velocity corresponds to the feedrate set in MD 32000: MAX_AX_VELO for the appropriate machine axis/axes.

**Bit 9 = 0** The override is active in JOG mode with handwheel.
**Bit 9 = 1** The override is always assumed to be 100% for JOG mode with handwheel regardless of how the override switch is set.

**Exception:** The override 0% is always active.

**Setting for DRF for all axes of the channel**
- **Bit 10 = 0** With DRF MD 11310: HANDWH_REVERSE is not active, i.e. the behavior is the same as with MD 11310 = 0.
- **Bit 10 = 1** With DRF MD 11310: HANDWH_REVERSE is active.

**Setting for the contour handwheel**
- **Bit 11 = 0** When the contour handwheel is deactivated, program execution is automatically continued.
- **Bit 11 = 1** When the contour handwheel is deactivated, an NC stop is automatically initiated. Only after input of NC-START, can the program execution be continued.
### 4.3 Axis/spindle-specific machine data

<table>
<thead>
<tr>

</tbody>
</table>

<table>
<thead>
<tr>
<th>Data type: DOUBLE</th>
<th>Applies from SW version: 1.1</th>
</tr>
</thead>
</table>

#### Significance:
The path of an increment which applies when an axis is traversed with the JOG keys in incremental mode or with the handwheel is defined in this MD.

The path covered by the axis on each increment each time the direction key is pressed or for each handwheel position is defined by the following parameters:

- MD: JOG_INCR_WEIGHT (weighting of an increment of a machine axis for INC/handwheel)
- Selected increment size (INC1, ..., INCVar)

The possible increment stages are defined globally for all axes in MD: JOG_INCR_SIZE_TAB [n] and in SD: JOG_VAR_INCR_SIZE.

Entering a negative value reverses the direction of the traverse keys and the handwheel rotation.

**SW 5 and higher:**
Default settings:
- JOG_INCR_WEIGHT[0]=0.001 mm (valid in metric measuring system)
- JOG_INCR_WEIGHT[1]=0.00254 mm (valid in inch measuring system and corresponds to 0.0001 inch)

#### MD irrelevant for .......
- Operating modes AUTOMATIC and MDA

<td>Rotary axis: mm/rev</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Data type: DOUBLE</th>
<th>Applies from SW version: 1.1</th>
</tr>
</thead>
</table>

#### Significance:
The axis velocity entered here applies when the rapid traverse override key is operated in JOG mode and when the axial feedrate override switch is set to 100%.

The value entered must not exceed the maximum permissible axis velocity (machine data MAX_AX_VELO).

This machine data is not used for the programmed rapid traverse G00.

**MD irrelevant for .......
- Operating modes AUTOMATIC and MDA

**Related to ....
- MD: MAX_AX_VELO (maximum axis velocity)
- MD: JOG_REV_VELO_RAPID (revolutional feedrate for JOG with rapid traverse override)

  - IS "Feedrate override" (DB21–28, DBB4)
### JOG_VELO

<table>
<thead>
<tr>
<th>MD number</th>
<th>JOG_VELO</th>
<th>Axis velocity in JOG mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>32020</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- **Default value:** 2000
- **Min. input limit:** 0
- **Max. input limit:** plus
- **Changes effective after Power On:**
- **Protection level:** 2
- **Unit:**
  - Linear axis: mm/min
  - Rotary axis: mm/rev
- **Data type:** DOUBLE
- **Applies from SW version:** 1.1
- **Significance:**
  - The value entered is the velocity traversed in JOG mode when the axial feedrate override switch is on position 100%.
  - This velocity is only used when general setting data JOG_SET_VELO = 0 is set for linear axes and linear feedrate (MD: JOG_REV.IS_ACTIVE = 0) or SD: JOG_ROT_AX.SET_VELO = 0 is set for rotary axes.
  - If this is the case, the axis velocity is active for:
    - continuous jogging
    - incremental jogging (INC1, ... INCvar)
    - handwheel jogging
  - The value entered must not exceed the maximum permissible axis velocity (machine data MAX_AX_VELO).
  - If DRF is active, the axis velocity for JOG must be reduced with MD: HANDWH_VELO_OVERLAY_FACTOR.
  - Spindles in JOG mode:
    - This machine data can also be used to define the JOG mode velocity for specific spindles (if SD: JOG_SPIND_SET_VELO = 0). However, the velocity can be modified with the spindle speed override switch.

- **Application:**
  - If different velocities/speeds have to be set for the individual axes/spindles traversing in JOG mode, this can be done for specific axes in this MD. SD: JOG_SET_VELO must be set to 0!

- **Related to ....**
  - MD: MAX_AX_VELO (maximum axis velocity)
  - MD: JOG_REV_VELO (revolutional feedrate for JOG)
  - MD: HANDWH_VELO_OVERLAY_FACTOR (ratio JOG velocity to handwheel velocity (DRF))
  - SD: JOG_SET_VELO (JOG velocity for G94)
  - SD: JOG_ROT_AX.SET_VELO (JOG velocity for rotary axes)
  - IS “Feedrate override” (DB21–28, DBB4)

### JOG_REV_VELO_RAPID

<table>
<thead>
<tr>

<th>JOG_REV_VELO_RAPID</th>
<th>Revoluntary feedrate in JOG mode with rapid traverse override</th>
</tr>
</thead>
<tbody>
<tr>
<td>32040</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- **Default value:** 2.5
- **Min. input limit:** 0
- **Max. input limit:** plus
- **Changes effective after Power On:**
- **Protection level:** 2
- **Unit:** mm/rev
- **Data type:** DOUBLE
- **Applies from SW version:** 1.1
- **Significance:**
  - The value entered in this MD defines the revoluntary feedrate of the axis in JOG mode with rapid traverse override referred to the revolutions of the master spindle.
  - This feedrate is active when SD: JOG_REV.IS_ACTIVE = 1. (Revolutional feedrate active with JOG.)

- **MD irrelevant for ....**
  - SD: JOG_REV.IS_ACTIVE = "0"

- **Related to ....**
  - SD: JOG_REV.IS_ACTIVE (revoluntary feedrate for JOG active)
  - MD: JOG_REV_VELO (revolutional feedrate with JOG)
### manual travel and handwheel travel (H1)

<tbody>
<tr>
<td>SMA_HANDWH_STOP_COND</td>
<td>Control of VDI signals in relation to handwheel</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Data type:** DWORD  
**Applies from SW version:** 3.2

**Significance:**
Definition of the behavior of the jogging with handwheel on axis-specific VDI interface signals:
- Bit==0: Interruption or collection of the distances preset via the handwheel
- Bit==1: Abort of the traversing movement or no collection

**Bit allocation**
- Bit 0: Feedrate override
- Bit 1: Spindle speed override
- Bit 2: Feedrate stop/spindle stop
- Bit 3: Clamping procedure running (==0 no effect)
- Bit 4: Controller enable
- Bit 5: Pulse enable

**For machine axis**

<table>
<thead>
<tr>
<th>Bit</th>
<th>Significance</th>

<td>The override is always assumed to be 100% for JOG mode with handwheel regardless of how the override switch is set. Exception: The override 0% is always active.</td>
</tr>
</tbody>
</table>

### 32090 HANDWH_VEL0_OVERLAY_FACTOR

<table>
<thead>
<tr>
<th>MD number</th>
<th>Description</th>
<th>Default value: 0.5</th>
<th>Min. input limit: 0</th>
<th>Max. input limit: plus</th>
<th>Changes effective after NEW_CONF</th>
<th>Protection level: 2</th>
<th>Unit: --</th>
</tr>
</thead>
<tbody>
<tr>
<td>HANDWH_VEL0_OVERLAY_FACTOR</td>
<td>Ratio JOG velocity to handwheel velocity (DRF)</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Data type:** DOUBLE  
**Applies from SW version:** 1.1

**Significance:**
The velocity active with the handwheel in DRF can be reduced in relation to the JOG velocity with this machine data.

The following applies for the velocity active with DRF:

- \( v_{DRF} = SD:JOG_SET_VEL0 \times MD:HANDWH_VEL0\_OVERLAY\_FACTOR \)
- \( v_{DRF} = MD:JOG_VEL0 \times MD:HANDWH_VEL0\_OVERLAY\_FACTOR \)

The velocity setting in SD: JOG_ROT_AXIS_SET_VEL0 applies for DRF on rotary axes instead of the value in SD: JOG_SET_VEL0.

**MD irrelevant for:** JOG handwheel

**Related to:**
- MD: JOG_VEL0 (JOG axis velocity)
- SD: JOG_SET_VEL0 (JOG velocity for G94)
- SD: JOG_AX_SET_VEL0 (JOG velocity for rotary axes)
### 4.4 General setting data

<table>
<thead>
<tr>
<th>41010</th>
<th>JOG_VAR_INCR_SIZE</th>
</tr>
</thead>
<tbody>
<tr>
<td>SD number</td>
<td>Size of variable increment for INC/handwheel</td>
</tr>
<tr>
<td>Default value: 0</td>
<td>Min. input limit: ***</td>
</tr>
<tr>
<td>Changes effective immediately</td>
<td>Protection level: MMC-MD 9220</td>
</tr>
<tr>
<td>Data type: DOUBLE</td>
<td>Applies from SW version: 1.1</td>
</tr>
</tbody>
</table>

**Significance:**

With this setting data the number of increments when variable increment (INCvar) is selected is defined. This increment size is traversed by the axis in JOG mode whenever the traverse key is pressed or the handwheel is turned one detent position and variable increment is selected (PLC interface signal “Active machine function: INC variable” for machine or geometry axis set to 1).

The defined increment size also applies to DRF.

**Note:** Please note that the increment size is active for incremental jogging and handwheel jogging. So if a large increment value is entered and the handwheel is turned the axis might cover a large distance (depends on setting in MD: JOG_INCR_WEIGHT).

**SD irrelevant for:**

JOG continuous

**Related to:**

IS “Active machine function: INC variable” (DB21–28, DBX41.5 ff)

or IS “Active machine function; INC variable” (DB31 – 48, DBX 69.5)

MD: JOG_INCR_WEIGHT (weighting of an increment for INC/handwheel)
### 41050 JOG_CONT_MODE_LEVELTRIGGRD

**SD number**: 41050

**Default value**: 1  
**Min. input limit**: 0  
**Max. input limit**: 1

**Changes effective immediately**:  
**Protection level**: MMC-MD 9220  
**Unit**: –

**Data type**: BOOLEAN  
**Applies from SW version**: 1.1

**Significance:**

1: Jog mode for JOG continuous  
   In jog mode (default setting) the axis traverses for as long as the traverse key is held down and an axis limitation has not been reached. When the key is released the axis is decelerated to zero velocity and the movement is considered completed.

0: Continuous mode for JOG continuous  
   In continuous mode the traverse movement is started with the first rising edge of the traverse key and continues to move when the key is released. The axis can be stopped again by pressing the traverse key again (second rising edge). The differences in axis traversing characteristics between the jog and continuous modes in JOG are described in detail in Section 2.1.

**SD irrelevant for ....**

Incremental jogging (JOG INC)  
Reference point approach (JOG REF)

### 41100 JOG_REV_IS_ACTIVE

**SD number**: 41100

**Default value**: 1  
**Min. input limit**: 0  
**Max. input limit**: 1

**Changes effective immediately**:  
**Protection level**: MMC-MD 9220  
**Unit**: –

**Data type**: BOOLEAN  
**Applies from SW version**: 1.1

**Significance:**

1: The axis (machine or geometry axis) is traversed in JOG mode at revolutional feedrate (G95) referred to the revolutions of the main spindle.

   The revolutional feedrate can be set as follows:
   - With global SD: JOG_REV_SET_VELO (only active when SD is not equal to 0)
   - With axial MD: JOG_REV VELO
   - With rapid traverse override with axial MD: JOG_REV_VELO_RAPID

0: The axis is traversed in JOG mode at linear feedrate (G94).

   The revolutional feedrate can be set as follows:
   - With global SD: JOG_SET_VELO (only active when SD is not equal to 0)
   - With axial MD: JOG_VELO
   - With rapid traverse override with axial MD: JOG_VELO_RAPID

**SD irrelevant for ....**

Operating modes AUTOMATIC and MDA

**Related to ....**

SD: JOG_REV_SET_VELO (JOG velocity for G95)  
MD: JOG_REV_VELO (revolutional feedrate with JOG)  
MD: JOG_REV_VELO_RAPID (JOG revolutional feedrate with rapid traverse)  
SD: JOG_SET_VELO (JOG velocity for G94)  
MD: JOG_VELO (JOG axis velocity)  
MD: JOG_VELO_RAPID (JOG rapid traverse)
### 41110 JOG_SET_VELO

<table>
<thead>
<tr>
<th>SD number</th>
<th>JOG_SET_VELO</th>
<th>JOG velocity for linear axes (for G94)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Default value: 0</td>
<td>Min. input limit: 0</td>
</tr>
<tr>
<td></td>
<td>Changes effective immediately</td>
<td>Protection level: MMC-MD 9220</td>
</tr>
<tr>
<td></td>
<td>Data type: DOUBLE</td>
<td>Applies from SW version: 1.1</td>
</tr>
</tbody>
</table>

**Significance:**
Value not equal to zero:
- The velocity value entered applies to linear axes traversed in JOG mode if linear feedrate (G94) is active for the relevant axis (MD: JOG_REV_IS_ACTIVE = 0).
- The axis velocity is active for:
  - continuous jogging
  - incremental jogging (INC1, ..., INCvar)
  - handwheel jogging
- The value entered is valid for all linear axes and must not exceed the maximum permissible axis velocity (MD: MAX_AX_VELO).

With DRF: If DRF is active, the velocity set in SD:JOG_SET_VELO must be reduced with MD: HANDWH_VELO_OVERLAY_FACTOR.

Value equal to zero:
- If 0 has been entered in the setting data, the active linear feedrate in JOG mode is MD: JOG_VELO “JOG axis velocity”. Each axis can be given its own JOG velocity with this MD (axial MD).

**SD irrelevant for:**
- For linear axes if SD: JOG_REV_IS_ACTIVE = 1
- For rotary axes (SD: JOG_ROT_AX_SET_VELO is active here)

**Application:**
The operator can define a JOG velocity for a particular application.

**Related to:**
- SD: JOG_REV_IS_ACTIVE (revolutional feedrate for JOG active)
- Axial MD: JOG_VELO (JOG axis velocity)
- Axial MD: MAX_AX_VELO (maximum axis velocity)
- Axial MD: HANDWH_VELO_OVERLAY_FACTOR (ratio JOG velocity to handwheel velocity (DRF))
- SD: JOG_ROT_AX_SET_VELO (JOG velocity for rotary axes)

### 41120 JOG_REV_SET_VELO

<table>
<thead>
<tr>
<th>SD number</th>
<th>JOG_REV_SET_VELO</th>
<th>JOG velocity (for G95)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Default value: 0</td>
<td>Min. input limit: 0</td>
</tr>
<tr>
<td></td>
<td>Changes effective immediately</td>
<td>Protection level: MMC-MD 9220</td>
</tr>
<tr>
<td></td>
<td>Data type: DOUBLE</td>
<td>Applies from SW version: 1.1</td>
</tr>
</tbody>
</table>

**Significance:**
Value not equal to zero:
- The velocity value entered applies to axes traversed in JOG mode if revolutional feedrate (G95) is active for the relevant axis (MD: JOG_REV_ISR_ACTIVE = 1).
- The axis velocity is active for:
  - continuous jogging
  - incremental jogging (INC1, ..., INCvar)
  - handwheel jogging
- The value entered is valid for all axes and must not exceed the maximum permissible axis velocity (MD: MAX_AX_VELO).

Value equal to zero:
- If 0 has been entered in the setting data, the active revolutionale feedrate in JOG mode is MD: JOG_REV_VELO “revolutional feedrate with JOG”.
- Each axis can be given its own revolutionale feedrate with this MD (axial MD).

**SD irrelevant for:**
- For axes if SD: JOG_REV_ISR_ACTIVE = 0

**Application:**
The operator can define a JOG velocity for a particular application.

**Related to:**
- Axial SD: JOG_REV_ISR_ACTIVE (revolutional feedrate for JOG active)
- Axial MD: JOG_REV_VELO (revolutional feedrate with JOG)
- Axial MD: MAX_AX_VELO (maximum axis velocity)

Signal Descriptions

5.1 General signals

5.1.1 Signals from NC

<table>
<thead>
<tr>
<th>DB10, DBB97, 98, 99</th>
<th>Channel number of geometry axis for handwheels 1, 2, 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data block</td>
<td>Signal(s) from NC (MMC → PLC)</td>
</tr>
<tr>
<td>Edge evaluation: no</td>
<td>Signal(s) updated: cyclically</td>
</tr>
<tr>
<td>Significance of signal:</td>
<td>Signal(s) valid from SW vers.: 2.1</td>
</tr>
</tbody>
</table>

The operator can assign an axis directly to the handwheel (1, 2, 3) on the operator panel. If this axis is a geometry axis (IS “Machine axis” = 0), the assigned channel number for the handwheel in question is transferred to the PLC.

In this way, the IS “Activate handwheel” is set for the selected geometry axis in accordance with the state set by the operator (IS “Handwheel selected”).

The following codes apply to the channel number:

<table>
<thead>
<tr>
<th>Bit 7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>Bit 0</th>
<th>Channel number</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>–</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>2</td>
</tr>
</tbody>
</table>

With machine axes (IS “Machine axis” = 1), the IS “Channel number geometry axis for handwheel 1, 2, 3” has no meaning.

For further information, see IS “Axis number for handwheel 1, 2, 3”.

Related to ....

- IS “Axis number of handwheel 1, 2, 3” (DB10, DBB100 ff)
- IS “Handwheel selected” (DB10, DBX100.6 ff)
- IS “Machine axis” (DB10, DBX100.7 ff)
- IS “Activate handwheel” (DB21, ... DBX12.0 – 12.2 ff)

Application

If DB10, DBB97 = 2, then handwheel 1 is assigned to channel 2.
### General signals

**DB10**

**DBB 100; 101; 102, Bits 0–4**

**Data block**

<table>
<thead>
<tr>

<th>Signal(s) valid from SW vers.: 1.1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Edge evaluation: no</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Significance of signal

The operator can assign an axis to every handwheel directly via the operator panel. To do so, he defines the required axis (e.g. X).

The basic PLC program provides the number of the axis plus the information 'machine axis or geometry axis' (IS "machine axis") as MMC interface signals.

The basic PLC program sets the interface signal "Activate handwheel" for the defined axis. Depending on the setting in MMC interface signal "machine axis" either the interface for the geometry axis or for the machine axis is used.

The following must be noted when assigning the axis designation to the axis number:

- IS "Machine axis" = 1; i.e. machine axis:
  - The assignment is made via MD: AXCONF_MACHAX_NAME_TAB [n] (machine axis name).
- IS "Machine axis" = 0; i.e. geometry axis:
  - The assignment is made via MD: AXCONF_GEOAX_NAME_TAB [n] (geometry axis name in channel). IS "Channel number geometry axis handwheel n" defines the channel assigned to the handwheel.

For following codes are used for the axis number:

<table>
<thead>
<tr>
<th>Bit 4</th>
<th>Bit 3</th>
<th>Bit 2</th>
<th>Bit 1</th>
<th>Bit 0</th>
<th>Axis number</th>
</tr>

### Plus and minus traverse keys for geometry axis (1,2,3)

<table>
<thead>
<tr>
<th>Signal state 1 or signal transition 0 → 1</th>
<th>The selected geometry axis can be traversed in both directions in JOG mode with the traverse keys plus and minus. Depending on the active machine function and the setting &quot;Jog or continuous mode&quot; (SD: JOG_CONT_MODE, MD: JOG_INC_MODE), the signal transition will cause different reactions.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Case 1:</strong> Continuous jogging with jog mode</td>
<td>The geometry axis traverses in the direction concerned as long as the interface signal is set to 1 (and as long as the axis position has not reached an activated limitation).</td>
</tr>
<tr>
<td><strong>Case 2:</strong> Continuous jogging with continuous mode</td>
<td>When the signal state first changes from 0 → 1, the geometry axis starts to traverse in the relevant direction. This traversing movement still continues even when the signal state changes from 1 → 0. A new signal state change from 0 → 1 (same travel direction!) will stop the traversing movement.</td>
</tr>
<tr>
<td><strong>Case 3:</strong> Incremental jogging with jog mode</td>
<td>With signal 1 the geometry starts to traverse at the set increment. If the signal changes to the 0 state before the increment is traversed, the traversing movement is interrupted. As soon as the signal state changes to 1 again the movement is continued. The geometry axis can be stopped and started several times as described above until the increment has been completely traversed.</td>
</tr>
<tr>
<td><strong>Case 4:</strong> Incremental jogging with continuous mode</td>
<td>When the signal state first changes from 0 → 1, the geometry starts to traverse at the set increment. If the signal state of the same traverse signal changes from 0 → 1, before the geometry axis has traversed the increment, the traverse movement is aborted. The increment is not traversed to the end.</td>
</tr>
</tbody>
</table>

If both traverse signals (plus and minus) are set at the same time there is no movement or a current movement is aborted!

The effect of the traverse keys can be disabled for every geometry axis individually with the PLC interface signal "Traverse key disable".

**Caution!** In contrast to machine axes, only one axis can be traversed at a time with the traverse keys. Alarm 20062 is triggered if an attempt is made to traverse more than one axis with the traverse keys.

### Signal state 0 or signal transition 1 → 0

See cases 1 to 4 above

### Signal irrelevant for....

Operating modes AUTOMATIC and MDA

### Special cases, errors,......

The geometry axis cannot be traversed in JOG mode:
- If it is already being traversed via the axial PLC interface (as a machine axis).
- If another geometry axis is already being traversed with the traverse keys.

Alarm 20062 "Axis already active" is output.

### Related to ....

IS "Traverse key disable for geometry axes" (DB21, ... DBX12.4 ff)
5.2 Channel-specific signals

### Machine function for geometry axis (1,2,3)

**DB21, ...**

**DBB13; 17; 21 Bits0–5**

**Data block**

**Signal(s) to channel (PLC → NCK)**

<table>
<thead>
<tr>
<th>Edge evaluation: no</th>
<th>Signal(s) updated: cyclically</th>
<th>Signal(s) valid from SW vers.: 1.1</th>
</tr>
</thead>
</table>

**Signal state 1 or signal transition 0 → 1**

This interface signal defines how many increments the geometry axis traverses when the traverse key is pressed or the handwheel is turned one detent position. JOG mode must be active for this (exception: with DRF).

The increment size is assigned to the interface signals as follows:

- INC1 to INC10000: with general machine data JOG_INCR_SIZE_TAB.
- INCvar: with general setting data JOG_VAR_INCR_SIZE

As soon as the selected machine function becomes active, this is signalled to the PLC interface (IS "Active machine function INC1;...").

If several machine function signals (INC1, INC... or "Continuous jogging") are selected at the interface simultaneously, no machine function is activated by the control.

**Signal state 0 or signal transition 1 → 0**

The machine function in question is not selected.

If an axis is currently traversing an increment, this movement is also aborted if this machine function is deselected or switched over.

**Related to ....**

IS "Active machine function INC1;..." for geometry axes (DB21, ... DBB41 ff)
IS "Machine function continuous" for geometry axes (DB21, ... DBX13.6 ff)

### "Continuous" machine function for geometry axis

**DB21, ...**

### 5.2.4 Description of signals from channel

#### DB21, ...

<table>
<thead>
<tr>
<th>Data block</th>
<th>DRF selected</th>
</tr>
</thead>
<tbody>
<tr>
<td>Signal(s) from channel (MMC → PLC)</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Edge evaluation: no</th>
<th>Signal(s) updated: cyclically</th>
<th>Signal(s) valid from SW vers.: 1.1</th>
</tr>
</thead>
</table>

*Signal state 1 or signal transition 0 → 1*

The operator has selected DRF on the operator panel. The PLC program (basic PLC program or user program) transfers this MMC interface signal as IS “Activate DRF” after logical combination. As soon as DRF is active, the DRF offset can be changed in AUTOMATIC or MDA mode using the handwheel assigned to the axis.

*Signal state 0 or signal transition 1 → 0*

The operator has not selected DRF on the operator panel.

*Signal irrelevant for.....*

JOG mode

Related to ....

IS: “Activate DRF” (DB21, ... DBX0.3)

#### DB21, ...

<table>
<thead>
<tr>

### 5.2 Channel-specific signals

#### Plus and minus travel commands (for geometry axis)

<table>
<thead>
<tr>
<th>Signal state 1 or signal transition 0 ——&gt; 1</th>
<th>A traverse movement of the axis is to be executed in one or the other direction. Depending on the mode selected, the command is triggered in different ways:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- JOG mode: with the plus or minus traverse key</td>
</tr>
<tr>
<td></td>
<td>- REF mode: with the traverse key that takes the axis to the reference point</td>
</tr>
<tr>
<td></td>
<td>- AUT/MDA mode: the program block containing a coordinate value for the axis in question is executed.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Signal state 0 or signal transition 1 ——&gt; 0</th>
<th>A travel command in the relevant axis direction has not been given or a traverse movement has been completed.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- JOG mode: The travel command is reset depending on the current setting &quot;jog or continuous mode&quot; (see interface signal &quot;Traverse keys plus and minus&quot;).</td>
</tr>
<tr>
<td></td>
<td>- While traversing with the handwheel.</td>
</tr>
<tr>
<td></td>
<td>- REF mode: When the reference point is reached</td>
</tr>
<tr>
<td></td>
<td>- AUT/MDA modes: The program block has been executed (and the next block does not contain any coordinate values for the axis in question)</td>
</tr>
<tr>
<td></td>
<td>- Abort with &quot;RESET&quot;, etc.</td>
</tr>
<tr>
<td></td>
<td>- IS &quot;Axis disable&quot; is active</td>
</tr>
</tbody>
</table>

**Application**

To release clamping of axes with clamping (e.g. on a rotary table).

**Note:** If the clamping is not released until the travel command is given, continuous-path operation of these axes is not possible!

**Related to ....**

IS: "Traverse key plus" and "Traverse key minus" for the geometry axis (DB21, DBX12.7 or DBX12.6 ff)

#### Active machine function for geometry axis (1, 2, 3)

<table>
<thead>
<tr>
<th>Signal state 1 or signal transition 0 ——&gt; 1</th>
<th>The PLC interface receives a signal stating which JOG mode machine function is active for the geometry axes.</th>
</tr>
</thead>
<tbody>

</tr>
</tbody>
</table>
### Traverse key disable

<table>
<thead>
<tr>
<th>DB31, ...</th>
<th>Traverse key disable</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DBX4.4</strong></td>
<td><strong>Signal(s) to axis/spindle (PLC -&gt; NCK)</strong></td>
</tr>
</tbody>
</table>

**Edge evaluation:** no
**Signal(s) updated:** cyclically
**Signal(s) valid from SW vers.:** 1.1

| Signal state 1 or signal transition 0 ——> 1 | The traverse keys plus and minus have no effect on the machine axes in question. It is thus not possible to traverse the machine axis in JOG with the traverse keys on the machine control panel. If the traverse key disable is activated during a traverse movement, the machine axis is stopped. |

| Signal state 0 or signal transition 1 ——> 0 | Traverse keys plus and minus are enabled. |

**Application**

It is thus possible, depending on the operating mode, to disable manual traverse of the machine axis in JOG mode with the traverse keys from the PLC user program.

**Related to **

IS "Traverse key plus" and "Traverse key minus" (DB31, ... DBX4.7 or DBX4.6)

### Rapid traverse override

<table>
<thead>
<tr>
<th>DB31, ...</th>
<th>Rapid traverse override</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DBX4.5</strong></td>
<td><strong>Signal(s) to axis/spindle (PLC -&gt; NCK)</strong></td>
</tr>
</tbody>
</table>

**Edge evaluation:** no
**Signal(s) updated:** cyclically
**Signal(s) valid from SW vers.:** 1.1

| Signal state 1 or signal transition 0 ——> 1 | If interface signal "Rapid traverse override" is set together with "Traverse key plus" and "Traverse key minus", the machine axis in question traverses at rapid traverse. The rapid traverse feedrate is defined in machine data JOG_VELO_RAPID. Rapid traverse override is active in the following JOG modes:
- Continuous jogging
- Incremental jogging
If rapid traverse override is active, the velocity can be modified with the rapid traverse override switch. |

| Signal state 0 or signal transition 1 ——> 0 | The machine axis traverses at the defined JOG velocity (SD: JOG_SET_VELO or MD: JOG_VELO). |

**Signal irrelevant for:** Operating modes AUTOMATIC and MDA
- Reference point approach (JOG mode)

**Related to **

IS "Traverse key plus" and "Traverse key minus" (DB31, ... DBX4.7 or DBX4.6)
IS "Axial feedrate/spindle speed override" (DB31, ... DBB0)
### 5.3 Axis/spindle-specific signals

<table>
<thead>
<tr>
<th>DB31, ... DBX4.7, 4.6</th>
<th>Plus and minus traverse keys</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data block</td>
<td>Signal(s) to axis/spindle (PLC -&gt; NCK)</td>
</tr>
<tr>
<td>Edge evaluation: yes</td>
<td>Signal(s) updated: cyclically</td>
</tr>
<tr>
<td>Signal state 1 or signal transition 0 ——&gt; 1</td>
<td>Signal irrelevant from SW vers.: 1.1</td>
</tr>
</tbody>
</table>

The selected machine axis can be traversed in both directions in JOG mode with the traverse keys plus and minus. Depending on the active machine function and the setting “Jog or continuous mode” (SD: JOG_CONT_MODE_LEVELTRIGGERD for JOG continuous and MD: JOG_INC_MODE_LEVELTRIGGERD for JOG INCR), the signal transition will cause different reactions.

**Case 1:** Continuous jogging with jog mode
The machine axis traverses in the direction concerned as long as the interface signal is set to 1 (and as long as the axis position has not reached an activated limitation).

**Case 2:** Continuous jogging with continuous mode
When the signal state first changes from 0 ——> 1, the geometry axis starts to traverse in the relevant direction. This traversing movement still continues even when the signal state changes from 1 ——> 0. A new signal state change from 0 ——> 1 (same travel direction!) stops the traversing movement again.

**Case 3:** Incremental jogging with jog mode
With signal 1 the machine axis starts to traverse at the set increment. If the signal changes to the 0 state before the increment is traversed, the traversing movement is interrupted. As soon as the signal state changes to 1 again the movement is continued.

**Case 4:** Incremental jogging with continuous mode
When the signal state first changes from 0 ——> 1, the machine axis starts traverse at the set increment. If the signal of the same traverse signal changes from 0 ——> 1, before the axis has traversed the increment, the traverse movement is aborted. The increment is not traversed to the end.

If both traverse signals (plus and minus) are set at the same time there is no movement or a current movement is aborted.

The effect of the traverse keys can be disabled for every machine axis individually with the PLC interface signal “Traverse key disable”.

**Signal state 0 or signal transition 0 ——> 0**
See cases 1 to 4 above

**Signal irrelevant for.....**
Operating modes AUTOMATIC and MDA

**Application**
The machine axis cannot be traversed in JOG mode if it is already being traversed via the channel-specific PLC interface (as a geometry axis). Alarm 20682 is triggered.

**Special cases, .....**
Indexing axes

**Related to ....**

</tr>
<tr>
<td></td>
<td>Signal(s) updated: cyclically</td>
</tr>
<tr>
<td></td>
<td>Signal(s) valid from SW vers.: 2.1</td>
</tr>
</tbody>
</table>

**Signal state 1 or signal transition 0 ——> 1**: The function "Handwheel override in AUTOMATIC mode" is active for the programmed positioning axis (FDA[AXi]). Handwheel pulses for this axis either act as a path setting (if FDA=0) or as a velocity override (if FDA>0) over the programmed axis feedrate. The interface signal is also set if "Handwheel override in AUTOMATIC mode" is active for a concurrent positioning axis (with FC15).

**Signal state 0 or signal transition 1 ——> 0**: The function "Handwheel override in AUTOMATIC mode" is not active for the programmed positioning axis (or concurrent positioning axis).

An active handwheel override is not active if:
- The positioning axis has reached the target position
- The distance-to-go is deleted by the axis-specific IS "Delete distance-to-go" (DBX2.2)
- A RESET is performed

**Related to IS "Activate handwheel" (DB31, DBX4.0 to DBX4.2)**

**Related to IS "Handwheel selected" (DB10, DBB100.6 ff)**
### 5.3 Axis/spindle-specific signals

<table>
<thead>
<tr>
<th>DB31, ...</th>
<th>Plus and minus traverse keys</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBX64.7, 64.6</td>
<td><strong>Signal(s) from axis/spindle (NCK → PLC)</strong></td>
</tr>

Brief Description

Purpose of compensation

The accuracy of machine tools is impaired as a result of deviations from the ideal geometry, power transmission faults and measuring system errors. Temperature differences and mechanical forces often result in great reductions in precision when large workpieces are machined.

Some of these deviations can usually be measured during installation and then compensated for during operation on the basis of values read by the positional actual-value encoder and other sensory devices.

Compensations

CNCs provide functions for compensation of the essential causes of error to meet the increasing demand for precision in machine tools.

The following compensation types can be activated for specific axes on the SINUMERIK 840D and FM-NC:

- compensation
- Backlash compensation
- Interpolatory compensation
  - LEC (leadscrew error and measuring system error compensation)
  - Beam sag compensation (compensation of beam sag and angular errors)
- Following error compensation (dynamic feedforward control)
- Friction compensation (or quadrant error compensation)
  - Conventional friction compensation
  - Quadrant error compensation with neural networks (SINUMERIK 840C only)
- Drift compensation for analog set speed (on SINUMERIK FM-NC only)
- Electronic counterweight for drives on SIMODRIVE 611D

These compensation functions can be set for each machine individually with axis-specific machine data.
The “Interpolatory compensation” function allows position-related dimensional deviations (for example, by leadscrew errors, measuring system errors or sag) to be corrected.

The compensation values are measured during installation and stored in a table as a position-related value. During operation the axis is compensated between interpolation points during linear interpolation.

The “friction compensation” function is particularly effective in achieving a significant improvement in contour accuracy in circular contour machining operations. If the direction of rotation of an axis changes, contour errors occur when the velocity equals zero (quadrant transition point) because of the changing friction conditions. “Friction compensation” (also called “Quadrant error compensation”) compensates for this error reliably the first time the contour is machined.

A neural network integrated in the SINUMERIK 840D adapts the optimum parameters in a self-learning process to compensate for friction, backlash or torsion. The system allows for simple, automatic re-optimization at any time.

The friction compensation system is installed most simply with a circularity test. The circular contour is followed and the actual position deviations from the programmed radius (most especially at the quadrant transition points) are measured and then displayed graphically. The circularity test is an “installation tool” function.

The compensations are active in all operating modes of the control as soon as the input data are available. Any compensations that require the position actual value are not activated until the axis reaches the reference point.

The normal actual-value and setpoint position displays ignore the compensation values and show the position values of an “ideal machine”. The compensation values are output in the “Service axes” display in the “Diagnosis” operating area.
Detailed Description

2.1 Temperature compensation

2.1.1 General

Heat generated by the drive equipment or high ambient temperatures (e.g. caused by sunlight, drafts) cause the machine base and parts of the machinery to expand. The degree of expansion depends on the temperature and the thermal conductivity of the machine parts.

Owing to the thermal expansion of the machinery, the actual positions of the axes change depending on temperature. Since this phenomenon impairs the accuracy of the machined workpieces, it is possible to compensate such temperature-related changes in actual value position (so-called temperature compensation).

Apart from the position actual values supplied by existing encoders, temperature compensation functions generally require a number of additional temperature sensors to acquire a temperature profile.

As temperature-related changes take a relatively long time to have an effect, acquisition and preprocessing of the temperature profile can be executed by the PLC in one-minute cycles.

In order to implement temperature compensation, the actual-value offsets over the positioning range of the axis must be measured at a given temperature (T) and plotted. This produces an error curve for this temperature value. Error curves must be produced for different temperatures.

The error curve characteristic shown in the figure below is frequently obtained. If a position reference point $P_0$ is chosen for the axis, an offset in the reference point (corresponds to the “position-independent component” of the temperature compensation) can be observed as the temperature changes, and because of the change in length an additional offset in the other position points which increases with the distance to the reference point (corresponds to the “position-dependent component” of the temperature compensation). 

---

Deformation due to temperature effects

Effects

Sensor technology

Error curves

Error curve characteristic
The error curve for a given temperature $T$ can generally be represented with sufficient accuracy by a straight line with a temperature-dependent gradient and reference position (see figure below).

![Error curve for temperature $T$](image)

**Fig. 2-1 Example of an error curve for heat expansion**

### Compensation equation

The compensation value $\Delta K_x$ is calculated on the basis of current actual position $P_x$ of this axis and temperature $T$ according to the following equation:

$$\Delta K_x = K_0(T) + \tan \beta(T) \times (P_x - P_0)$$

**Key to letters (see figure below):**

- $\Delta K_x$: Temperature compensation value of axis at position $P_x$
- $K_0$: Position-independent temperature compensation value of axis
- $P_x$: Actual position of axis
- $P_0$: Reference position of axis
- $\tan \beta$: Coefficient of the position-dependent temperature compensation (corresponds to the gradient of the approximated error line)

The compensation values are acquired in interpolation cycles. If the compensation value $\Delta K_x$ is positive, the axis moves in the negative direction.

![Approximated error line](image)

**Fig. 2-2 Approximated error line for temperature compensation**
Since the approximated error line applies only to the instantaneous temperature value, the parameters of the error lines that are newly generated when the temperature rises or falls must be sent to the NCK again. Only in this way can expansion due to heat be compensated for effectively.

2.1.2 Temperature compensation parameters

Error curves for different temperatures can be defined for each axis, as illustrated in the figure above. For each error curve the following parameters must be determined and then entered in the setting data:

- Position-dependent temperature-compensation value $K_0$
  SD 43900: TEMP_COMP_ABS_VALUE
- Reference position $P_0$ for position-dependent temperature compensation
  SD 43920: TEMP_COMP_REF_POSITION
- Slope $\tan \theta$ for position-dependent temperature compensation
  SD 43910: TEMP_COMP_SLOPE
### Activate temperature compensation

Temperature compensation can be activated for every axis by means of axial MD 32750: TEMP_COMP_TYPE. The type of temperature compensation to be applied can also be selected.

#### Table 2-1  MD 32750: TEMP_COMP_TYPE

<table>
<thead>
<tr>
<th>MD 32750: TEMP_COMP_TYPE</th>
<th>Meaning</th>
<th>Associated parameters</th>

<td>SD 43900: TEMP_COMP_ABS_VALUE SD 43920: TEMP_COMP_REF_POSITION SD 43910: TEMP_COMP_SLOPE</td>
</tr>
</tbody>
</table>

### Activation

The following conditions must be fulfilled before temperature compensation can be applied:

1. The option must be enabled.
2. The compensation type must be selected (MD 32750: TEMP_COMP_TYPE).
3. The parameters for the compensation type are defined.
4. The axis must be referenced (IS “Referenced/synchronized 1 or 2” DB31 to 48, DBX60.4 or 60.5 = ‘1’).  

As soon as these conditions are fulfilled, the temperature compensation value for the current position actual value is added to the setpoint in all modes and the machine axis is traversed.

If the reference position is subsequently lost again, e.g. because the encoder frequency has been exceeded (IS “Referenced/Synchronized 1 or 2” = 0), then the compensation processing routine is aborted.

### Modify parameters

When temperature T changes, the parameters which are temperature-dependent, i.e. \((K_0, \tan \theta, P_0)\), also change and can thus always be overwritten by the PLC.

It is thus possible for the machine-tool manufacturer to represent the mathematical and technological relationship between the axis positions and temperature values via the PLC user program and thus calculate the various parameters for the temperature compensation. The temperature parameters are transferred to the NCK with various Services (FB2 (GET) “Read data” and FB3 (PUT) “Write data”).

For more information on handling and parameterization of FB2 and FB3 see: References: /FB/, P3 “Basic PLC Program”.

Compensations (K3)

2.1 Temperature compensation

Axial MD 32760: COMP_ADD_VELO_FACTOR (velocity violation due to compensation) can be set to limit the maximum compensation value that can be added to the specified velocity value in each IPO clock cycle.

This machine data limits the maximum gradient of the error curve. If the maximum gradient is exceeded, the compensation value is limited in the control.

To prevent overloading of the machine or tripping of monitoring functions in response to step changes in the above parameter settings, the compensation values are distributed among several IPO clock cycles by an internal control function as soon as they exceed the maximum compensation value specified for each cycle (MD 32760: COMP_ADD_VELO_FACTOR).

The normal actual-value and setpoint position displays ignore the compensation values and show the position values of an ideal machine.

The total compensation value calculated from the temperature and sag compensation functions belonging to the current actual position is output in the “Service axes” display in the “Diagnosis” operating area.

Installation of the temperature compensation is described below using the example of a Z axis on a lathe.

In order to determine the temperature-dependent error characteristic of the Z axis, proceed as follows:

- Constant heating by traversing the axis across the whole Z axis traversing range (in the example: from 500 mm to 1500 mm)
- Measuring the axis position in distances of 100 mm
- Measuring the actual temperature at the leadscrew
- Executing a traversing measuring cycle every 20 minutes

The mathematical and technological relationship and the resulting parameters for temperature compensation are derived from the recorded data. The error deviations measured in relation to the axis position measured by the NC are displayed graphically in the figure below.
2.1 Temperature compensation

The temperature compensation parameters must now be set on the basis of the measurement results (see figure above).

**Reference position \( P_0 \)**

As the figure above illustrates, there are basically two methods of configuring reference position \( P_0 \):

1. \( P_0 = 0 \) with position-independent temperature compensation value \( K_0 \neq 0 \)
2. \( P_0 \neq 0 \) with position-independent temperature compensation value \( K_0 = 0 \)

In our example, variant 2 is chosen, where the position-independent temperature compensation value is always 0. The temperature compensation value therefore only consists of the position-dependent components. The following parameters result:

- \( MD \ 32750: \ \text{TEMP\_COMP\_TYPE} = 2 \) (only position-dependent temperature compensation is active)
- \( P_0 = 320 \text{ mm} \rightarrow SD \ 43920: \ \text{TEMP\_COMP\_REF\_POSITION} = 320 \)
2.1 Temperature compensation

**Coefficient \( \tan \beta \) (T)**

In order to determine the dependency of coefficient \( \tan \beta \) of the position-dependent temperature compensation on the temperature, the error curve gradient is plotted against the measured temperature (see figure below).

![Coefficient \( \tan \beta \) (T) graph](image)

**Fig. 2-4** Characteristic of coefficient \( \tan \beta \) as a function of measured temperature T

Depending on the resulting line, the following dependency on T results for the coefficient \( \tan \beta \):

\[
\tan \beta (T) = (T - T_0) \cdot \frac{TK_{\max}}{T_{\max} - T_0}
\]

where
- \( T_0 \) = Temperature where the position-dependent error = 0
- \( T_{\max} \) = Maximum measured temperature
- \( TC_{\max} \) = Temperature coefficient for \( T_{\max} \)

The results are as follows with reference to the figure above:

For
- \( T_0 = 23 \) degrees
- \( T_{\max} = 42 \) degrees
- \( TC_{\max} = 270 \mu m/1000 \) mm

Therefore:

\[
\tan \beta(T) = (T - 23 \text{ degrees}) \cdot 14.21 \left[ \frac{\mu m}{1000 \text{ mm}} \right]
\]

Example: for \( T = 32.3 \) degrees \( \rightarrow \) \( \tan \beta = 132 \mu m/1000 \) mm

The coefficient \( \tan \beta \) (T) for every measured temperature T can be calculated easily in the PLC according to the above equation and then transferred to the NCK as SD 43910: TEMP_COMP_SLOPE.
2.2 Backlash compensation

Mechanical backlash

Slight backlash generally occurs in the power train between a moving machine part and its drive (e.g. leadscrew) since an unacceptably high level of machine wear would occur if the mechanical components were to be set to be absolutely free of backlash. For this reason backlash can arise between the machine part and the measuring system.

Effects

Mechanical backlash on axes/spindles with indirect measuring systems causes the travel path to be falsified. For example, when an axis reverses direction, its travel distance is reduced or increased by an amount corresponding to the backlash (see the two figures below).

Compensation

To compensate for backlash, the axis-specific actual value is corrected by the amount of backlash every time the axis/spindle changes direction. This quantity can be entered in MD: 32450 BACKLASH during installation of every axis/spindle. If there is a second measuring system installed for the axis/spindle, the relevant backlash values must be entered for each measuring system.

In SW 5 and later, the backlash can be weighted by a factor as a parameter set function. The weighting factor is set in MD 32452: BACKLASH_FACTOR to between 0.01 and 100.0, default setting is 1.0.

Example application: Compensation of gear-stage-related backlash.

Activation

Backlash compensation is always active in all operating modes after reference point approach.

Position display

The normal actual-value and setpoint position displays ignore the compensation values and show the position values of an "ideal machine".

Display of compensation values

The compensation value applying to the current actual position is output as the total compensation calculated from “LEC” and “backlash compensation” in the “Service axes” display in the “Diagnosis” operating area.

Positive backlash

The encoder “leads” the machine part (e.g. table). Since the actual position acquired by the encoder also “leads” the real actual position of the table, the table travels too short a distance (see figure below). The backlash compensation value must be entered as a positive value here (= normal case).
2.2 Backlash compensation

Positive backlash (normal case)

Encoder actual value is ahead of the real actual value (table): the table does not travel far enough.

Fig. 2-5  Positive backlash (normal case)

Negative backlash

The encoder “lags behind” the machine part (e.g. table); the table then travels too far (see figure below). The correction value entered is negative.

Fig. 2-6  Negative backlash

2nd measuring system

If there is a second measuring system for the axis/spindle, a backlash compensation must be entered for this too. As the second measuring system is mounted in a different way from the first measuring system, the backlash can be different from that of the first measuring system.

When the measuring system is switched over the associated compensation value is always activated.

Note

The actual-value difference between the two encoders must not exceed the value stored in axis-specific MD 36500 ENC_CHANGE_TOL (maximum tolerance for position actual-value changeover).
2.3 Interpolatory compensation

2.3.1 General

**Compensation methods**

The following compensation methods are applied in order to implement “interpolatory compensation”:

1. “Leadscrew error compensation” or “Measuring system error compensation”, which from now on will be referred to as **leadscrew error compensation (LEC)**.

2. Beam sag compensation or angularity error compensation (Software Version 2 and higher), which from now on will be referred to as **beam sag compensation**.

Many of the characteristics of these two compensation methods are identical and are therefore described in the next Section “General notes”.

**Terms**

The following terms are used in the description of “Interpolatory compensation”:

- **Compensation value** The difference between the axis position measured by the position actual-value encoder and the required programmed axis position (= axis position of the ideal machine). The compensation value is often also referred to as the “correction” value.

- **Basic axis** Axis whose setpoint or actual value position forms the basis of the calculation of a compensation value.

- **Compensation axis** Axis whose setpoint or actual position is modified by a compensation value.

- **Interpolation point** A position of the base axis and the corresponding compensation value of the compensation axis.

- **Correction table** Table containing interpolation points.

- **Compensation relations** Assignment of the base axis and the corresponding compensation axis and the reference to the corresponding compensation table.

**Leadscrew and measuring system errors**

The measuring principle of “indirect measurement” on NC-controlled machines is based on the assumption that the leadscrew pitch is constant at any given point within the traversing range so that the actual axis position can be derived from the position of the drive spindle (ideal case).

However, manufacturing tolerances result in dimensional deviations of varying degrees of severity on spindles (so-called “leadscrew errors”).

To these are added the deviations caused by the measuring system used (differing divisions) and by the way the measuring system is mounted on the machine (measuring system errors) and any machine-dependent sources of error.
**Sag errors**

Weight can result in position-dependent displacement and inclination of moved parts since it can cause machine parts and their guides to sag (see Fig. 3.2).

Large workpieces, too, e.g. cylinders, sag under their own weight.

**Angularity errors**

If moving axes are not positioned in exactly the required angle (e.g. perpendicular) with respect to one another, increasingly serious positioning errors will occur as the deviation from zero point becomes greater.

**Compensation table**

Since the deviations in dimension caused by the phenomena described above have a direct effect on workpiece machining accuracy, they need to be compensated by appropriate position-dependent correction values. The compensation values are derived from measured error curves and entered in the control in the form of compensation tables during installation. A separate table must be created for each compensation relation.

The compensation values and additional table parameters are entered in the compensation tables using special system variables.

---

**Note**

Compensation tables can be loaded only if MD 32700: ENC_COMP_ENABLE (interpolatory compensation)=0 and/or MD 32710: CEC_ENABLE (enable beam sag compensation) are set to zero.

---

**Input of compensation table**

The size of the compensation table, i.e. the number of interpolation points, must first be defined in a machine data – a Power On must then be executed.

Compensation tables can be loaded to the backed-up NC user memory by two different methods.

- The compensation values are loaded when an NC program with the compensation tables is started.
- The compensation values can also be loaded by transferring the tables from a PC via the serial interface on the MMC.

---

**Note**

Once the size of the compensation tables has been defined in machine data, the NC generates the tables after the next Power On. The default setting for these tables is “0”.

The compensation tables can be output from the “Services” operating area via the serial interface on the MMC and loaded back after editing.
These compensation values are not lost when the control is switched off because they are stored in the non-volatile user memory. They can be updated if necessary (e.g. as a result of re-measuring because of machine ageing).

Caution

When MD 18342: MM_CEC_MAX_POINTS[t] (max. number of interpolation points of beam sag comp., SRAM) or MD 38000: MM_ENC_COMP_MAX_POINTS (number of interpolation points for interpolatory comp., SRAM) is changed, the buffered NC user memory is re-initialized when the system powers up. All user data of the battery-buffered user memory (e.g. drive and MMC machine data, tool offsets, part programs, compensation tables etc.) are deleted.

References: /FB/, S7, “Memory Configuration”

Archiving

Compensation tables are not saved with the series start-up file.

To archive compensation tables, they must be output via the serial interface on the MMC. The following compensation types can be selected for archiving in the operating area “Services”, “Data OUT”

- LEC/measuring system error compensation (%_N_AX_EEC_INI)
- Beam sag/angularity compensation (%_N_AX_CEC_INI)
- Quadrant error compensation (%_N_AX_QEC_INI)

Compensation tables can also be saved as an archive file with an MMC 102/103.

Linear interpolation between interpolation points

The traversing path to be compensated delineated by the start and end positions is divided up into several (number depends on error curve shape) path segments of equal size (see figure below). The actual positions that limit these sub-paths are designated “interpolation points”. A compensation value must be entered for each interpolation point (actual position) during installation. The compensation value applied between 2 interpolation points is generated on the basis of linear interpolation using the compensation values for the adjacent interpolation points (i.e. adjacent interpolation points are linked along a line).
### 2.3 Interpolatory compensation

#### Compensation value at reference point

The compensation table should be structured such that the compensation value at the reference point is “zero”.

---

#### 2.3.2 Measuring system error compensation (MSEC)

**Function**

The leadscrew error compensation function is part of the measuring system error compensation system.

In “Measuring system error compensation” (from now on referred to as MSEC), the base and compensation axes are always identical. It is therefore an axial compensation for which a definition of the base axis and compensation axis in the compensation table is not necessary.

The principle of the MSEC is to modify the axis-specific position actual value by the assigned compensation value in the interpolation cycle and to apply this value to the machine axis for immediate traversal. A positive compensation value causes the corresponding machine axis to move in the negative direction.

The magnitude of the compensation value is not limited and is not monitored. In order to avoid impermissibly high velocities and accelerations caused by compensation, small compensation values must be selected. Large compensation values can cause other axis monitoring functions to output alarms (e.g. contour monitoring, velocity setpoint limitation).

If the axis to be compensated has a 2nd position measuring system, a separate compensation table must be created and activated for each measuring system. The correct table is automatically used when switching between measuring systems.
The “MSEC” does not become active until the following conditions are fulfilled:

- The compensation values are stored in the NC user memory and active (after Power On).
- The function has been activated for the machine axis concerned (MD 32700: ENC_COMP_ENABLE [e] = 1). If compensation is required for a 2nd measuring system, this must also be enabled with the above machine data (e = 0: 1. measuring system; e = 1: 2. measuring system).
- The axis has been referenced (IS: “Referenced/synchronized 1 or 2” DB31, ... DBX60.4 or 60.5 = ‘1’).

As soon as these conditions have been fulfilled, the axis-specific actual value is altered by the compensation value in all modes and traversed by the machine axis immediately.

If the reference is then lost, e.g. because the encoder frequency has been exceeded (IS “Referenced/synchronized 1 or 2” = ‘0’), compensation processing is deactivated.

For every machine axis and for every measuring system (if a 2nd measuring system is installed), the number of reserved interpolation points of the compensation table must be defined and the necessary memory reserved in MD 38000: MM_ENC_COMP_MAX_POINTS.

\[
\text{MD 38000: } $\text{MM ENC COMP MAX POINTS}[e,AXi] \\
\text{with: } AXi = \text{axis name e.g. X1, Y1, Z1} \\
e = \text{measuring system } (e = 0: 1. \text{ measuring system}; e = 1: 2. \text{ measuring system})
\]

\[
\text{MM ENC COMP MAX POINTS}[e, AXi] = \frac{\text{SAA ENC COMP MAX}[e, AXi]}{\text{SAA ENC COMP STEP}[e, AXi]} + 1
\]

The position-related compensation values are stored in the form of system variables for the relevant axis in the compensation table.

The following measuring-system-specific parameters must be set for the table (see figure below):

- **Compensation value for interpolation point N in compensation table** ($\text{SAA ENC COMP}[e,N,AXi]$)
  
  For every individual interpolation point (axis position) the compensation value must be entered in the table.

  Interpolation point N is limited by the number of possible interpolation points in the relevant compensation table (MD 38000: MM_ENC_COMP_MAX_POINTS).

  The magnitude of the compensation value is not limited.
  Permissible limit of N: $0 \leq N < \text{MM ENC COMP MAX POINTS} - 1$

**Note**

The first and last compensation values remain active over the entire traversing range, i.e. these values should be set to “0” if the compensation table does not cover the entire traversing range.
2.3 Interpolatory compensation

- **Distance between interpolation points** ($\text{AA\_ENC\_COMP\_STEP}[e,AXi])
  The distance between interpolation points corresponds to the distance between the compensation values in the relevant compensation table (see above for meaning of e and AXi).

- **Initial position** ($\text{AA\_ENC\_COMP\_MIN}[e,AXi])
  The initial position is the axis position at which the compensation table for the relevant axis begins ($\neq$ interpolation point 0).

  The compensation value for the initial position is $\text{AA\_ENC\_COMP\_STEP}[e,0,AXi])$.

  For all positions smaller than the initial position the compensation value of interpolation point zero is used (does not apply for table with modulo).

- **End position** ($\text{AA\_ENC\_COMP\_MAX}[e,AXi])
  The end position is the axis position at which the compensation table for the relevant axis ends ($\neq$ interpolation point k).

  The compensation value for the end position is $\text{AA\_ENC\_COMP\_STEP}[e,k,AXi])$.

  The compensation value of interpolation point k is used for all positions larger than the end position (exception: table with modulo functions).

  The number of required interpolation points is calculated as follows:

  $$ k = \frac{\text{AA\_ENC\_COMP\_MAX} - \text{AA\_ENC\_COMP\_MIN}}{\text{AA\_ENC\_COMP}} $$

  With $0 \leq k < \text{MD 38000: MM\_ENC\_COMP\_MAX\_POINTS}$

  The following conditions apply to interpolation point k:

  - With $k = \text{MD 38000: MM\_ENC\_COMP\_MAX\_POINTS} - 1$
    - the compensation table is fully utilized!
  - With $k = \text{MD 38000: MM\_ENC\_COMP\_MAX\_POINTS} - 1$
    - the compensation table is not fully utilized; compensation values entered in the table greater than k have no effect.

  - With $k = \text{MD 38000: MM\_ENC\_COMP\_MAX\_POINTS} - 1$
    - the compensation table is limited internally by reducing the end position; the compensation values greater than k are not used.

- **Compensation with modulo function** ($\text{AA\_ENC\_COMP\_IS\_MODULO}[e,AXi])
  When the compensation is activated with a modulo function, the compensation table is repeated cyclically, i.e. the compensation value at location $\text{AA\_ENC\_COMP\_MAX} (= \text{interpolation point } \text{AA\_ENC\_COMP}[e,k,AXi])$ is followed immediately by the compensation value at location $\text{AA\_ENC\_COMP\_MIN} (= \text{interpolation point } \text{AA\_ENC\_COMP}[e,0,AXi])$.

  For rotary axes with modulo 360° it is therefore suitable to program 0° as the initial position position ($\text{AA\_ENC\_COMP\_MIN}$) and 360° as the end position ($\text{AA\_ENC\_COMP\_MAX}$).
The compensation values entered for these two positions should be the same as otherwise the compensation value jumps from MAX to MIN at the transition point and vice versa.

\[
\text{\$AA\_ENC\_COMP\_IS\_MODULO}[e,AXi] = 0: \text{Compensation without modulo function}\n\]

\[
\text{\$AA\_ENC\_COMP\_IS\_MODULO}[e,AXi] = 1: \text{Compensation with modulo function}\n\]

---

**Caution**

When the compensation values are entered it is important that all interpolation points be assigned a position value within the defined range (i.e. no gaps). Otherwise, the previous valid position value is used for these interpolation points!

---

**Note**

Table parameters which contain position information are not automatically converted at measuring system change (change in MD 10240: SCALING_SYSTEM_IS_METRIC) in Software Version 4 and lower. The position information is always interpreted in the current measuring system. Conversions must be conducted externally.

In Software Version 5 and higher, by setting MD 10260: CONVERT_SCALING_SYSTEM=1. External conversion is no longer necessary.

**References:** /FB1/, G2, Chapter 2

---

**Example**

The following example shows compensation value inputs for machine axis X1.

%_N_AX_EEC_INI
CHANDATA (1)

\[
\text{\$AA\_ENC\_COMP}[0,0,X1] = 0.0 ; 1. compensation value ( = interpolation point 0) +0\mu m
\]

\[
\text{\$AA\_ENC\_COMP}[0,1,X1] = 0.01 ; 2. compensation value ( = interpolation point 1) +10\mu m
\]

\[
\text{\$AA\_ENC\_COMP}[0,2,X1] = 0.012 ; 3. compensation value ( = interpolation point 2) +12\mu m
\]

\[
\text{\$AA\_ENC\_COMP}[0,800,X1] = –0.0 ; \text{last compensation value ( = interpolation point 800)}
\]

\[
\text{\$AA\_ENC\_COMP\_STEP}[0,X1] = 1.0 ; \text{Distance between interpolation points 1.0 mm}
\]

\[
\text{\$AA\_ENC\_COMP\_MIN}[0,X1] = –200.0 ; \text{Compensation begins at –200.0 mm}
\]

\[
\text{\$AA\_ENC\_COMP\_MAX}[0,X1] = 600.0 ; \text{Compensation ends at +600.0 mm}
\]

\[
\text{\$AA\_ENC\_COMP\_IS\_MODULO}[0,X1] = 0; \text{Compensation without modulo function}
\]

M17
In this example, the number of compensation interpolation points set in MD 38000: MM_ENC_COMP_MAX_POINTS ≥ must be 801 or else alarm 12400 “Element does not exist” will be output.

The compensation table for this example requires at least 6.4 Kbytes of the non-volatile NC user memory (8 bytes per compensation value).

Fig. 3-1 Compensation table parameters (system variables for MSEC)
2.3.3 Sag compensation and angularity error compensation

Function

In contrast to the MSEC, the base and compensation axes need not be identical for “Sag compensation” or “Angularity error compensation”, requiring an axis assignment in every compensation table.

In order to compensate for sag of one axis (base axis) which results from its own weight, the absolute position of another axis (compensation axis) must be influenced. “Sag compensation” is therefore an inter-axis compensation.

As illustrated in the figure below, the further the machining head moves in the negative Y1 axis direction, the more the cross-arm sags in the negative Z1 axis direction.

The error must be recorded in the form of a compensation table that contains a compensation value for the Z1 axis for every actual value position in the Y1 axis. It is sufficient to enter the compensation values for the interpolation points.

When the Y1 axis traverses, the control calculates the corresponding compensation value in the Z1 axis in interpolation cycles performing linear interpolation for positions between the interpolation points. This compensation is sent to the position control loop as an additional setpoint. A positive compensation value causes the corresponding machine axis to move in the negative direction.

![Fig. 3-2 Example of sag caused by own weight](image)

Depending on the requirement, several compensation relations can be defined for one axis. The total compensation value results from the sum of all the compensation values of this axis.
Setting options

The many ways in which the compensation value for sag compensation can be produced/influenced are listed below (see figure below).

1. An axis can be defined as the input variable (base axis) for several compensation tables (settable via system variables).

2. An axis can be defined as the recipient of the output variable (compensation axis) of several compensation tables (settable via system variable). The total compensation value is derived from the sum of the individual compensation values.

   The following definitions apply for the maximum number of possible compensation tables:
   - Maximum number of tables available in total for all axes:
     \[2 \times \text{maximum number of axes of system}\]
   - Maximum number of tables that can affect one compensation axis:
     \[\text{maximum number of axes of the system}\]

3. An axis can be both a base axis and a compensation axis at any one time. The programmed (required) position setpoint is always used to calculate the compensation values.

4. The range of influence of the compensation (starting and end position of the base axis) and the distance between the interpolation points can be defined for every compensation table (settable via system variables).

5. Compensation can be direction-dependent (settable via system variables).

6. Every compensation table has a modulo function for cyclic evaluation (settable via system variables).

7. A weighting factor by which the table value is multiplied (definable as a setting data which can therefore be altered by the part program, PLC or the user at any time) can be introduced for every compensation table.

8. Compensation tables can be multiplied in pairs (settable via system variables). The product added to the total compensation value of the compensation axis.

9. The compensation can be activated in the following ways:
   - With MD 32710: CEC_ENABLE [AXi] the sum of all compensation relations is enabled for machine axis AXi.
   - With SD 41300: $SN_CEC_TABLE_ENABLE[t]$, evaluation of the compensation table \[t\] is enabled.

   It is thus possible, for example, to alter the compensation relations either from the part program or from the PLC user program (e.g. switching over the tables), depending on the machining requirements.

10. In SW 5 and higher, when MD 10260: CONVERT_SCALING_SYSTEM=1 is set, the axial MD 32711: CEC_SCALING_SYSTEM_METRIC becomes effective. The measuring system for all tables effective for this axis is set in this machine data. Hereby all position entries are interpreted together with the calculated total compensation value in the configured measuring system. External conversions of position information are no longer necessary with a measuring system change.

Note

No compensation table becomes active until the base axis and compensation axis have been referenced.
2.3 Interpolatory compensation

Monitoring

To avoid excessive velocities and acceleration rates on the machine axis as a result of applying sag compensation, the total compensation value is monitored and limited to a maximum value. The maximum compensation value is set in axial MD 32720: CEC_MAX_SUM on an axis-specific basis.

If the resulting total compensation value is greater than the maximum value, alarm 20124 “Sum of compensation values too high” is output. Program processing is not interrupted. The compensation value output as an additional set-point is limited to the maximum value.

Alteration of the total compensation value is also limited axially. When limit value MD 32730: CEC_MAX_VELO is exceeded, alarm 20125 “Compensation value changed too quickly” is output; again program processing is continued. The path not covered because of the limitation is made up as soon as the compensation value is no longer subject to limitation.
2.3 Interpolatory compensation

Fig. 3-3 Generation of compensation value for sag compensation
2.3  Interpolatory compensation

Complex compensation

Since it is possible to use the position of an axis as the input quantity (base axis) for several tables, to derive the total compensation value of an axis from several compensation relationships (tables) and to multiply tables, it is also possible to implement sophisticated and complex beam sag and angularity error compensation systems.

This function also makes it possible to deal with different error sources efficiently. For example, it is possible to combine a table with a modulo function for a periodic recurring error component with a second table without a modulo function for an aperiodic error component for the same axis.

Leadscrew errors can also be compensated with this function by parameterizing an identical axis for the base and compensation axes. However, in contrast to the MSEC, measuring-system switchovers are not automatically registered in this case.

Activation

The beam sag compensation function does not become active until the following conditions are fulfilled:

- The option “Interpolatory compensation” has been enabled.
- The function has been activated for the relevant machine axis (compensation axis).
  (MD 32710: CEC_ENABLE [AXi] = 1).
- The compensation values have been stored in the non-volatile NC user memory and are active (after Power On).
- Evaluation of the relevant compensation table has been enabled (SD 41300: CEC_TABLE_ENABLE [t] = 1)
- The current measuring system of the base and compensation axes has been referenced (IS: “Referenced/Synchronized 1 or 2” DB31, ... DBX60.4 or 60.5 = ‘1’).

As soon as these conditions have been fulfilled the setpoint position of the compensation axis is altered in all modes with reference to the setpoint position of the base axis and the corresponding compensation value and is then immediately traversed by the machine axis.

If the reference is then lost, e.g. because the encoder frequency has been exceeded (IS “Referenced/Synchronized 1 or 2” = ‘0’), compensation processing is deactivated.

Compensation interpolation points

The number of required interpolation points in the compensation table must be defined for every compensation relationship and the requisite memory space reserved in general MD 18342: MM_CEC_MAX_POINTS.

MD 18342: $MN_MM_CEC_MAX_POINTS[t]$
with:  \[ t = \text{Index of compensation table} \]
with  \( 0 \leq t < 2 \times \text{maximum number of axes} \)
  i.e.  \( t = 0: 1. \text{ compensation table} \)
  \( t = 1: 2. \text{ compensation table etc.} \)

\[
MM_CEC_MAX_POINTS[t] = \frac{SAN_CEC_MAX[t] - SAN_CEC_MIN[t]}{SAN_CEC_STEP[t]} + 1
\]
### Table parameters

The position-related corrections for the relevant compensation relationship are stored as system variables in the compensation table.

The following parameters must be set for the table (see Fig. 3.1):

- **Compensation value for interpolation point N in compensation table \([t]\) \((\text{\$AN\_CEC} [t, N])\)**
  
  The compensation value of the compensation axis must be entered in the table for each individual interpolation point (position of the base axis).

  Interpolation point \(N\) is limited by the number of possible interpolation points in the relevant compensation table (MD 18342: MM\_CEC\_MAX\_POINTS).

  Permissible range of \(N\): 0 \(\leq\) \(N\) < MD 18342: MM\_CEC\_MAX\_POINTS

- **Base axis \((\text{\$AN\_CEC\_INPUT\_AXIS}[t])\)**
  
  Name of machine axis whose setpoint is to be used as the input for the compensation table \([t]\).

- **Compensation axis \((\text{\$AN\_CEC\_OUTPUT\_AXIS}[t])\)**
  
  Name of machine axis to which the output of the compensation table \([t]\) is to be applied.

---

**Note**

In multi-channel systems the “general axis identifiers” AX1... must be preset, if the identifiers of machine axis and channel axis are identical.

- **Distance between interpolation points \((\text{\$AN\_CEC\_STEP}[t])\)**
  
  The distance between interpolation points defines the distance between the input values for the compensation table \([t]\).

- **Initial position \((\text{\$AN\_CEC\_MIN}[t])\)**
  
  The initial position is the position of the base axis at which the compensation table \([t]\) begins \((=\) interpolation point 0\).

  The compensation value for the initial position is \(\text{\$AN\_CEC} [t, 0]\).

  The compensation value of interpolation point 0 is used for all positions smaller than the initial position (exception: table with modulo functions).

- **End position \((\text{\$AN\_CEC\_MAX}[t])\)**
  
  The end position is the position of the base axis at which the compensation table \([t]\) ends \((=\) interpolation point \(k\)).

  The compensation value for the end position is \(\text{\$AN\_CEC} [t, k]\).

  The compensation value of interpolation point \(k\) is used for all positions larger than the end position (exception: table with modulo functions).

  The number of required interpolation points is calculated as follows:

  \[
  k = \frac{\text{\$AN\_CEC\_MAX}[t] - \text{\$AN\_CEC\_MIN}[t]}{\text{\$AN\_CEC\_STEP}[t]}
  \]

  With 0 \(\leq\) \(k\) < MD 18342: MM\_CEC\_MAX\_POINTS

  The following conditions apply to interpolation point \(k\):

  - With \(k\) = MD 18342: MM\_CEC\_MAX\_POINTS - 1
    
    \[\Rightarrow\] the compensation table is fully utilized!
2.3 Interpolatory compensation

- With $k < \text{MD 18342: MM_CEC_MAX_POINTS} - 1$
  - the compensation table is not fully utilized; the entered compensation values greater than k have no effect.

- With $k > \text{MD 18342: MM_CEC_MAX_POINTS} - 1$
  - the compensation table is limited in the control by reducing the end position; the compensation values greater than k are not used.

- **Direction-dependent compensation ($\text{SAN_CEC_DIRECTION}[t]$)**
  This system variable can be used to define whether the compensation table [t] should apply to both travel directions of the base axis or only either the positive or negative direction.
  
  - 0: Table affects both traversing directions of the base axis
  - 1: Table only affects the positive traversing direction of the base axis
  - -1: Table only affects the negative traversing direction of the base axis

Possible applications: Position-dependent backlash compensation can be implemented using two tables, one of which affects the positive traversing direction, the other of which affects the negative traversing direction of the same axis.

- **Table multiplication ($\text{SAN_CEC_MULT_BY_TABLE}[t]$)**
  This option allows the compensation values of any table to be multiplied with those of another (or with themselves). The product is added as an additional compensation value to the total compensation value of the compensation table.

Syntax: $\text{SAN_CEC_MULT_BY_TABLE}[t_1] = t_2$

  - $t_1 =$ Index of table 1 of the compensation axis
  - $t_2 =$ Number of table 2 of the compensation axis.

  It is important to ensure that the number and index of the same table are different!

  The general rule is: Table number = table index + 1

- **Compensation with modulo function ($\text{SAN_CEC_IS_MODULO}[t]$)**
  When the compensation with modulo function is activated, the compensation table is repeated cyclically, i.e. the compensation value at location $\text{SAN_CEC_MAX}[t]$ (interpolation point $\text{SAN_CEC}[t,k]$) is followed immediately by the compensation value at location $\text{SAN_CEC_MIN}[t]$ (interpolation point $\text{SAN_CEC}[t,0]$).

  These two compensation values should be the same as otherwise the compensation value jumps from MAX to MIN at the transition point and vice versa.

  - $\text{SAN_CEC_IS_MODULO}[t] = 0$: Compensation without modulo function
  - $\text{SAN_CEC_IS_MODULO}[t] = 1$: Compensation with modulo function

If modulo compensation is to be implemented with a modulo rotary axis as base axis, the compensation table used has to be modulo calculated as well.

Example:

MD 30300: IS_ROT_AX[AX1] = 1: Rotary axis
MD 30310: ROT_IS_MODULO[AX1] = 1: Modulo 360°
$\text{SAN_CEC_INPUT_AXIS}[0]=\text{AX1}$
$\text{SAN_CEC_MIN}[0]=0.0$
$\text{SAN_CEC_MAX}[0]=360.0$
$\text{SAN_CEC_IS_MODULO}[0]=1$
2.3 Interpolatory compensation

Note
Table parameters which contain position information are not automatically converted at measuring system change (change in MD 10240: SCALING_SYSTEM_IS_METRIC) in SW 4 and lower. The position information is always interpreted in the current measuring system. Conversions must be conducted externally.

In SW 5 and higher, by setting MD 10260: CONVERT_SCALING_SYSTEM=1 you can configure the measuring system via MD 32711: CEC_SCALING_SYSTEM. External conversions of position information are no longer necessary with a measuring system change.

References: /FB1/, G2, Chapter 2

Example of table
The following example shows a compensation table for sag compensation of the Y1 axis. Depending on the position of the Y1 axis, a compensation value is applied to the Z1 axis. The 1st compensation table (t = 0) is used for this.

%_N_NC_CEC_INI
CHANDATA (1)
$AN_CEC [0,0] = 0 ; 1. compensation value ( = interpolation point 0) for Z1: ±0\mu m
$AN_CEC [0,1] = 0.01 ; 2. compensation value ( = interpolation point 1) for Z1: +10\mu m
$AN_CEC [0,2] = 0.012 ; 3. compensation value ( = interpolation point 2) for Z1: +12\mu m
...
$AN_CEC [0,100] = 0 ; last compensation value ( = interpolation point 101) for Z1: ±0\mu m
$AN_CEC_INPUT_AXIS[0] = (AX2) ; Base axis Y1
$AN_CEC_OUTPUT_AXIS[0] = (AX3) ; Compensation axis Z1
$AN_CEC_STEP[0] = 8 ; Distance between interpolation points 8.0 mm
$AN_CEC_MIN[0] = -400.0 ; Compensation begins at -400 mm
$AN_CEC_MAX[0] = 400.0 ; Compensation ends at Y1 = +400 mm
$AN_CEC_DIRECTION[0] = 0 ; Table applies to both directions of travel of Y1
$AN_CEC_MULT_BY_TABLE[0] = 0 ; Compensation without modulo function
$AN_CEC_IS_MODULO[0] = 0 ;
M17

In this example, the number of compensation interpolation points set in MD 18342: MM_CEC_MAX_POINTS[0] must be 101; otherwise alarm 12400 is output.

The compensation table for this example requires at least 808 bytes of non-volatile NC user memory.

Table multiplication
With the table multiplication function, any table can be multiplied with any other table (i.e. even with itself). The multiplication link is established using the system variables described above.
The following example for the compensation of machine foundation sagging illustrates an application of table multiplication.

On large machines, sagging of the foundations can cause inclination of the whole machine. For the boring mill in the second figure below, for example, it is determined that compensation of the X1 axis is dependent both on the position of the X1 axis itself (since this determines angle of inclination $\beta(X1)$) and on the height of the boring mill (i.e. the position of the Z1 axis).

To implement compensation, the compensation values of the X1 and Z1 axes must be multiplied according to the following equation (see figure below):

$$\Delta X1 = Z1 \cdot \sin(\beta(X1)) \approx Z1 \cdot \beta(X1)$$

Compensation table 1 (table index = 0) describes the reaction of axis X1 on axis X1 (sine of the position-dependent tilting angle $\beta(X1)$).

Compensation table 2 (table index = 1) describes the reaction of axis Z1 on axis X1 (linear).

In table 1, the multiplication of table 1 (index = 0) with table 2 is to be selected:

$\text{AN_CEC_MULT_BY_TABLE[0]} = 2$

Compensation of sag in a machine base
The compensation values of the z axis sag on flat bed machines are often measured in practice at various points as a function of the x and y coordinates. Where such conditions need to be met, it is useful to enter the measured compensation values according to a grid-type distribution. The interpolation points with the relevant compensation values are positioned on the intersections of the grid (x–y plane). Compensation values between these interpolation points are interpolated linearly by the control.

The following example explains in more detail how sag and angularity compensation can be implemented by a grid of 4 x 5 (lines x columns) in size. The size of the whole grid is 2000x900mm². The compensation values are each measured in steps of 500mm along the x axis and 300mm along the y axis.

Note
The maximum dimensions of the grid (number of lines and columns) depends on the following points:

No. of lines: Dependent on number of axes in the system (dependent on NCU type)

No. of columns: Dependent on the maximum number of values which can be entered in a compensation table (up to a total of 2000 values)

Caution
The number of lines and columns is set in MD 18 342: MM_CEC_MAX_POINTS. The machine data is memory-configuring.

Fig. 3-6 Compensation values of z axis with chessboard-like distribution of x-y plane
2.3 Interpolatory compensation

Basic principle

The compensation values cannot be entered directly as a 2-dimensional grid. Compensation tables in which the compensation values are entered must be created first.

A compensation table contains the compensation values of one line (four lines in the example, i.e. four compensation tables). Compensation values 0.1 to 0.5 are entered in the first table in the example and compensation values 0.6 to 1.0 in the second (see Fig. 3-6). Compensation tables are referred to below as f tables and the table values as \( f_i(x) \) (i = number of table).

The compensation values of f tables are evaluated by multiplying them with other tables. The latter are referred to below as g tables and their values as \( g_i(y) \). The number of f tables and g tables is equal (four in the example).

In g tables, one compensation value in each table is set to 1 and all the others to 0. The position of compensation value 1 within the table is determined by the table number. In the first g table, compensation value 1 is positioned at the first interpolation point and, in the second g table, at the second interpolation point, etc. By multiplying g tables with f tables, the correct compensation value in each f table is selected by multiplying it with 1. All irrelevant compensation values are concealed through multiplication with 0.

Using this scheme, compensation value \( D_z \) at position \( (x/y) \) is calculated according to the following equation:

\[
D_z(x/y) = f_1(x) g_1(y) + f_2(x) g_2(y) + \ldots
\]

When the compensation value for the current position of the machine spindle is calculated, the f table values are multiplied by the g table values according to this rule.

Applied to the example, this means, for instance, that compensation value \( D_z(500/300) \) is calculated by multiplying each of the function values \( f_i(500) \) in the f tables with the function values \( g_i(300) \) in the g tables:

\[
D_z(500/300) = f_1(1000) g_1(300) + f_2(1000) g_2(300) + f_3(1000) g_3(300) + f_4(1000) g_4(300)
\]

\[
D_z(500/300) = 0.2 \times 0 + 0.7 \times 1 + 1.2 \times 0 + 1.7 \times 0 = 0.7
\]

(for functions values, see also f and g tables in program code)

Program code

The application example described above can be achieved with the following part program code:

```plaintext
$MA_CEC_ENABLE[Z1] = FALSE ; Deactivate the compensation by setting to FALSE, allowing the table values to be altered without generating alarm 17070.
NEWCONF ; Activate $MA_CEC_ENABLE

M17
2.3.4 Special features of interpolatory compensation

Measurement
The “Measurement” function supplies the compensated actual positions (ideal machine) required by the machine operator or programmer.

TEACH IN
The “TEACH IN” function also uses compensated position values to determine the actual positions to be stored.

Software limit switches
The ideal position values (i.e. the position actual values corrected by the MSEC and backlash compensation functions) are also monitored by the software limit switches.

Position display
The position actual-value display in the machine coordinate system shows the ideal (programmed) actual position value of the axis (ideal machine).

In the axis/spindle service display (operating area Diagnosis) the positional value determined by the measuring system plus the sum of the backlash compensation and leadscrew error compensation is displayed (= actual position value measuring system 1/2).

Compensation value display
The following compensation values are also output in the “Axes” service display (Diagnosis operating area):

<table>
<thead>
<tr>
<th>Axes service display</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Absolute compensation value measuring system 1 or 2</td>
<td>Display value corresponds to the total compensation value calculated from “MSEC” and “Backlash compensation” for the current actual position of the axis (measuring system 1 or 2).</td>
</tr>
<tr>
<td>Compensation value beam sag/temperature</td>
<td>Display value is the sum of the compensation values from “beam sag compensation” and “temperature compensation” for the current actual position of the axis.</td>
</tr>
</tbody>
</table>

References: /FB1/, D1, “Diagnostic Tools”

Reference point loss
If the reference point for the base axis is lost (IS: “Referenced/Synchronized 1 or 2” DB31, ... DBX60.4 or 60.5 = ’0’), the MSEC and backlash compensation functions are deactivated in the affected axes. When the reference point is reached these compensations are automatically switched on again.

Protection of access to compensation tables
There is currently no protection against access to the compensation tables.
2.3 Interpolatory compensation

**Controller enable**
As a result of the compensation relationship, a traversing movement by the base axis may also cause the compensation axis to move, making it necessary for controller enable signals to be set for these axes (PLC user program). Otherwise the compensation only has a limited effect.

**Travel commands to PLC**
The traversing signals are output in response to every change in compensation value to give the axis the opportunity to open its brakes (which, for example, operate as a function of travel commands).
2.4 Following error compensation (feedforward control)

2.4.1 General

Axial following errors

The axial following error can be reduced almost to zero with the help of the feedforward control. This feedforward control is therefore also called "following error compensation".

The following error causes undesired velocity-dependent contour errors especially during acceleration at contour curves, e.g. arcs and corners.

Feedforward control methods

The following feedforward control methods can be used to implement "following error compensation":

- Velocity feedforward control (SINUMERIK 840D and FM-NC) (included in the basic version)
- Torque feedforward control (on SINUMERIK 840D) (option)

The selection is made in MD 32620: FFW_MODE (feedforward control method).

Note

The torque feedforward control method cannot be used for the combination SINUMERIK 840Di and SIMODRIVE 611U drive.

Activation/deactivation in part program

The feedforward control can also be activated and deactivated by means of the following high-level language elements in the part program:

- FFWON Feedforward control ON
- FFWOF Feedforward control OFF

The default setting (i.e. M30 even after Reset) is entered in channel-specific MD 20150: GCODE_RESET_VALUES (initial setting of G groups).

MD 32630: FFW_ACTIVATION_MODE defines for each axis whether the feedforward control can be switched on with FFWON or off with FFWOF.

FFWON and FFWOF are used to activate and deactivate respectively the feedforward control of all axes/spindles in the channel for which MD 32630: FFW_ACTIVATION_MODE = 1 is set (as well as MD 32620: FFW_MODE = 1 or 2).

MD 32630: FFW_ACTIVATION_MODE should therefore have identical settings for axes that interpolate with each other.

The feedforward control should only be switched on or off while the axis/spindle is stationary to prevent jerk. This is the responsibility of the programmer.
The following points should be noted before the feedforward control is applied:

- Rigid machine behavior
- Precise knowledge about the machine dynamic response
- No sudden changes in the position and speed setpoints

The feedforward control is set on an axis/spindle-specific basis. First of all, the current control loop, speed control loop and position control loop must be set to an optimum for the axis/spindle.

References:
- /IAF/, Installation and Start-Up Guide SINUMERIK FM-NC
- /IAD/, Installation and Start-Up Guide SINUMERIK 840D

MD 32620: FFW_MODE must first be set to select the desired feedforward control mode.

- 0 = No feedforward control
- 1 = Speed feedforward control (default setting)
- 2 = Torque feedforward control (only possible with SINUMERIK 840D)
  The option must be enabled before torque feedforward control is selected.

The feedforward control parameters must then be assigned to the relevant axis/spindle and then entered in the machine data.

### 2.4.2 Speed feedforward control

In the case of speed feedforward control, a velocity setpoint is also applied directly to the input of the speed controller (see figure below). This additional setpoint can be weighted by a factor that must equal approximately “1” as standard.

In order to achieve a correctly set speed feedforward control, the equivalent time constant of the speed control loop must be determined exactly and entered as a machine data.
Compensations (K3)

2.4 Following error compensation (feedforward control)

Fig. 3-7  Speed feedforward control
2.4 Following error compensation (feedforward control)

**Parameters**

The following axis-specific parameters must be defined for the speed feedforward control during installation:

- MD 32610: `VELO_FFW_WEIGHT`
  Feedforward control factor
- MD 32810: `EQUIV_SPEEDCTRL_TIME`
  Equivalent time constant of the closed speed control loop

**Parameters for speed feedforward control**

**MD 32810: `EQUIV_SPEEDCTRL_TIME`**

Equivalent time constant of closed speed control loop

The equivalent time constant of the closed speed control loop is determined by measuring the step response of the speed control loop. With the 611D, the setting process can be displayed using the installation tools.

**References:**
/IAF/, “Installation and Start-Up Guide”
/IAD/, “Installation and Start-Up Guide”

The equivalent time constant of the speed control loop can also be generated from the position control cycle (=basic system cycle x factor for position control cycle) plus the speed setpoint filter (drive machine data 1500 ... 1521).

On the SINUMERIK FM-NC, for example, a speed setpoint jump can be generated using a battery box or an analog function generator. The equivalent time constant must be determined as exactly as possible.

**MD 32610: `VELO_FFW_WEIGHT`**

Feedforward control factor for speed feedforward control

If the control loop for axis/spindle is optimally set and the equivalent time constant has been determined exactly, the feedforward control factor will be approximately 1. Therefore the initial value to be entered in the machine data is 1 (= standard default setting).

With this value the following error will be reduced to nearly zero (i.e. control deviation is 0) when speed is constant. This should be checked by making positioning movements and looking at the actual resulting control deviation shown on the service display.

**References:**
/IFB/, D1, “Diagnostic Tools”

**Fine adjustment**

By making fine adjustments to the values set in MD 32610: `VELO_FFW_WEIGHT` and MD 32810: `EQUIV_SPEEDCTRL_TIME`, it is possible to set the desired response for the relevant axis/spindle.
This is done by traversing the axis/spindle at a constant velocity and checking the affect of the changes made in the machine data in the service display “Control deviation”. The adjustment criterion for the speed feedforward control is “control deviation” = 0.

Case 1: When the axis is traversed in the positive direction the “control deviation” displays a positive value.

⇒ The equivalent time constant of the speed control loop or the feedforward factor is too small

Case 2: When the axis is traversed in the positive direction the “control deviation” displays a negative value.

⇒ The equivalent time constant of the speed control loop or the feedforward control factor is too large

A small acceleration and a large feedrate should be chosen so that the values can be easily read on the service display. This produces very long acceleration phases from which it is easy to read off the control deviation.

An example with axis X:

MD 32300: MAX_AX_ACCEL = 0,1 ; m/s^2
MD 32000: MAX_AX_VELO = 20000,0 ; mm/min

; Part program for setting the equivalent time constant
G1 F20000
FFWON
LOOP:
X1000
X0
GOTOB LOOP
M30

Example for active speed feedforward control of axes 1, 2 and 3.

Equivalent time constant of the speed control loop (MD 32810: EQUIV_SPEEDCTRL_TIME) for

• Axis 1: 2 ms
• Axis 2: 4 ms (dynamically the slowest axis)
• Axis 3: 1 ms

The values for the time constant of the dynamic response adaptation (MD 32910: DYN_MATCH_TIME) are then as follows for:

• Axis 1: 2 ms
• Axis 2: 0 ms
• Axis 3: 3 ms

References: /FB/, G2, “Velocities, Setpoint/Actual-Value Systems, Closed-Loop Control”
2.4 Following error compensation (feedforward control)

**Lead time with speed setpoint**

Transfer of speed setpoints to the drive can be set in machine data MD 10082 and MD 10083.

### Note

It is only possible to fix the lead time for output of speed setpoints with the digital 611D drives.

The lead time for output of speed setpoints is determined in MD 10082: CTRLOUT_LEAD_TIME. The larger the value entered, the sooner the drive transfers the speed setpoints.

This means that:

- **0 %**: Setpoints are transferred at the beginning of the next position control cycle
- **50 %**: Setpoints are already transferred after execution of half of the position control cycle

A reasonable lead time can only be determined by measuring the maximum position control calculating time. MD 10083: CTRLOUT_LEAD_TIME_MAX suggests a value measured by the control. As this is a net value, it is advisable for the user to provide for a safety allowance of, for example, 5 %.

### Note

If lead times that are input are too high, this can cause output of drive alarm 300506.

The input value is rounded to the next lower speed controller pulse rate in the drive. If the speed controller pulse rate settings of the drives are different, changing the value will not necessarily lead to the same degree of controller improvement for all configured drives.
2.4.3 Torque feedforward control (not 840Di)

In the case of torque feedforward control, an additional current setpoint proportional to the torque is applied directly to the current controller input (see figure below). This value is formed using the acceleration and moment of inertia.

In order to achieve a correctly set torque feedforward control, the exact equivalent time constant must be determined and entered in the machine data.

Because of the direct current setpoint injection, torque feedforward control is only possible with digital drives (SINUMERIK 840D).

Parameters

The following axis-specific parameters must be defined during installation for torque feedforward control:

- **MD 32650: AX_INERTIA**
  Moment of inertia of the axis for torque feedforward control (from the point of view of the drive)

- **MD 32800: EQUIV_CURRCTRL_TIME**
  Equivalent time constant of current control loop

- **SIMODRIVE 611D-MD 1004: CTRL_CONFIG**
  Configuration structure
  Set bit 0 = “1” (torque feedforward control active)
### 2.4 Following error compensation (feedforward control)

#### Parameters for torque feedforward control

*(available only on SINUMERIK 840D)*

**SIMODRIVE 611D MD 1004: CTRL_CONFIG** configuration structure

The torque feedforward control is activated in the SIMODRIVE 611D with bit 0 = “1”.

**MD 32800: EQUIV_CURRCTRL_TIME**

Equivalent time constant of closed current control loop

The equivalent time constant of the closed current control loop is determined by measuring the step response of the current control loop. With the SIMODRIVE 611D, the settling process can be displayed using the installation tools.

In addition, the current setpoint of the 1st drive of each module on the DA converter of the module is output so that it can also be observed with an oscilloscope.

**References:** /IAD/, “Installation and Start-Up Guide”

The equivalent time constant must be determined as exactly as possible.

**MD 32650: AX_INERTIA**

Total moment of inertia of the axis

The total moment of inertia (moment of inertia of drive + load referred to the motor shaft) of the axis must be determined and entered in the MD for torque feedforward control.

1 to 2 times the SIMODRIVE 611D-MD 1117: MOTOR_INERTIA (motor moment of inertia) is the recommended initial value setting for MD 32650: AX_INERTIA.

**Fine adjustment**

By making fine adjustments to the values set in MD 32800: EQUIV_CURRCTRL_TIME and MD 32650: AX_INERTIA, it is possible to set the desired response for the relevant axis/spindle.

Because acceleration is very fast the service display cannot be used to finely adjust the parameters. In the case of the SIMODRIVE 611D, for example, changes made to the machine data should be checked by recording the following error from an analog setpoint output (this can only be done with the installation tool).

It is important to observe the following error against constant travel even when the axis/spindle is accelerating.

The adjustment criterion for torque feedforward control is Following error = 0

**Case 1:** When the axis is traversed in the positive direction the following error shows a **positive** value.

⇒ The values entered for the equivalent time constant of the current control loop or for the moment of inertia of the axis are **too small**

**Case 2:** When the axis is traversed in the positive direction the following error shows a **negative** value.

⇒ The values entered for the equivalent time constant of the current control loop or for the moment of inertia of the axis are **too large**
### 2.4 Following error compensation (feedforward control)

| Setting for interpolating axes | The feedforward control parameters must be set optimally for each axis even in the case of interpolating axes. The axes can have different feedforward control settings. |
| Check contour monitoring       | The two equivalent time constants (MD 32810: EQUIV_SPEEDCTRL_TIME and MD 32800: EQUIV_CURRCTRL_TIME) influence the contour monitoring which should therefore subsequently be checked. |
| References: /FB/ A3, “Axis Monitoring, Protection Zones” |
| Effect on servo gain factor    | When the feedforward control is set correctly, the response to setpoint changes in the controlled system under speed feedforward control is as dynamic as that of the speed control loop or, under torque feedforward control, as that of the current control loop, i.e. the servo gain factor set in MD 32200: POS_CTRLGAIN has very little influence on the response to setpoint changes (e.g. corner errors, overshoots, circle/radius errors). On the other hand, feedforward control does not affect the disturbance characteristic (synchronism). In this case, the factor set in MD 32200: POS_CTRLGAIN is the active factor. |
| Service display “Servo gain factor” | When a feedforward control is active, the servo gain of the axis (corresponds to servo gain factor applied to response to setpoint changes) shown in the Service display is very high. |
| Dynamic response adaptation    | For axes that interpolate with one another, but with different axial control loop response times, dynamic response adaptation can be used to achieve identical time responses of all axes to ensure optimum contour accuracy without loss of control quality. When a feedforward control is active, the difference between the equivalent time constants of the “slowest” speed or current control loop for the relevant axis must be entered as the time constant of the dynamic response adaptation (MD 32910: DYN_MATCH_TIME). |
2.5 Friction compensation (quadrant error compensation)

2.5.1 General

Function
Friction occurs predominantly in the gearing and guideways. Static friction is especially noticeable in the machine axes. Because it takes a greater force to initiate a movement (breakaway) than to continue it, a greater following error occurs at the beginning of a movement.

The same phenomenon occurs on a change of direction where static friction causes a jump in frictional force. If, for example, one axis is accelerated from a negative to a positive velocity, it sticks for a short time as the velocity passes through zero because of the changing friction conditions. With interpolating axes, changing friction conditions can cause contour errors.

Quadrant errors
This behavior is particularly apparent on circular contours on which one axis is moving at maximum path velocity and the other is stationary at quadrant transitions. With the aid of friction compensation these so-called “quadrant errors” can be almost completely eliminated.

Principle
Measurements on machines have shown that contour errors caused by static friction can be effectively compensated by the injection of an additional setpoint pulse with the correct sign and amplitude.

Friction compensation methods
One of two friction compensation methods can be selected on the SINUMERIK 840D (MD 32490: FRICT_COMP_MODE “Type of friction compensation”):

- Conventional friction compensation (MD 32490: FRICT_COMP_MODE = 1)

  With this type, the intensity of the compensation pulse can be set according to the characteristic as a function of the acceleration. This characteristic must be determined and parameterized during start-up using the circularity test. The procedure for this is relatively complicated and requires some experience.

  Conventional friction compensation can also be used with SINUMERIK FM-NC.

- Quadrant error compensation with neural networks
  (option on SINUMERIK 840D) (MD 32490: $MA_FRICT_COMP_MODE = 2)

  To simplify start-up, the compensation characteristic no longer has to be set manually by the start-up engineer but is determined automatically during a training phase and then stored in the non-volatile user memory.

  The neural network can reproduce a compensation curve of much better quality and precision.
The function also allows simple automatic re-optimization directly at the machine.

### Circularity test

The friction compensation function (both conventional and neural friction compensation) can be started up most easily by means of a circularity test. This is done by following a circular contour, measuring the actual position and representing the deviations from the programmed radius (especially at the quadrant transition points) graphically. The measurements are recorded using a “Trace” that is stored in the passive file system.

This circularity test is a function of the “Installation tool”. With the MMC101 or MMC102/103, this function can be selected directly in the Diagnosis area. See Section 2.7 for more detailed information about the circularity test.

### 2.5.2 Conventional friction compensation

#### Method of friction compensation

Conventional friction compensation is selected by entering the value 1 in MD 32490: FRICT_COMP_MODE (friction compensation type).

#### Amplitude adaptation

In many cases, the injected amplitude of the friction compensation value does not remain constant over the whole acceleration range. For example, for optimum compensation with high accelerations, a smaller compensation value must be injected than for smaller accelerations. For this reason, friction compensation with adapted injection amplitude can be activated in cases where high accuracy is required (see figure below). The function is activated axis-specifically in MD 32510: FRICT_COMP_ADAPT_ENABLE = 1 (adaptation for friction compensation active).

![Fig. 3-9 Typical curve for friction compensation with amplitude adaptation](image-url)
The adaptation characteristic is divided into four ranges (a different injection amplitude $\Delta n$ is applied in each range):

B1: for $a < a_1$  \[ \Delta n = \Delta n_{\text{max}} \cdot \frac{a}{a_1} \]

B2: for $a_1 \leq a \leq a_2$  \[ \Delta n = \Delta n_{\text{max}} \]

B3: for $a_2 < a < a_3$  \[ \Delta n = \Delta n_{\text{max}} \cdot \left(1 - \frac{(a - a_2)}{(a_3 - a_2)}\right) \]

B4: for $a \geq a_3$  \[ \Delta n = \Delta n_{\text{min}} \]

**Characteristic parameters**

The parameters of the adaptation characteristic in the figure above must be entered as machine data for specific axes.

$\Delta n$ = Injection amplitude of the friction compensation value

$\Delta n_{\text{max}}$ = Maximum friction compensation value

$\Delta n_{\text{min}}$ = Minimum friction compensation value

- $a_1$ = Adaptation acceleration value 1 for friction compensation
- $a_2$ = Adaptation acceleration value 2 for friction compensation
- $a_3$ = Adaptation acceleration value 3 for friction compensation

**Note about shape of characteristic**

In special cases, the calculated characteristic may deviate from the typical shape illustrated in the figure above. In some cases, the value for $\Delta n_{\text{min}}$ (MD 32530: FRICT_COMP_CONST_MIN) may even be greater than $\Delta n_{\text{max}}$ (MD 32520: FRICT_COMP_CONST_MAX).

### 2.5.3 Start-up of conventional friction compensation

**Circularity test**

The friction compensation function can be started up most easily by means of a circularity test. Here, deviations from the programmed radius (especially at the quadrant transitions) can be measured and displayed while traversing a circular contour.

**Step-by-step start-up**

The conventional friction compensation function must first be selected. (MD 32490: FRICT_COMP_MODE=1).

The friction compensation value mainly depends on the machine configuration. Installation is performed in two stages.

- Stage 1: Calculation of the compensation values without adaptation

- Stage 2: Calculation of the adaptation characteristic (if the friction compensation is dependent on the acceleration and the results of stage 1 are not satisfactory).
Installation stage 1: Friction compensation without adaptation

1. Circularity test without friction compensation

A circularity test without friction compensation (MD 32500: FRICT_COMP_ENABLE = 0) should be performed first. The procedure for performing a circularity test is described in Section 2.7.

A typical characteristic of quadrant transitions without friction compensation is shown in the figure below.

![Fig. 3-10 Uncompensated radius deviation at quadrant transitions](image)

2. Enabling the friction compensation

After this, the friction compensation must be activated for the axis/spindle in question.

Activate friction compensation

⇒ MD 32500: FRICT_COMP_ENABLE[n] = 1

3. Deactivate adaptation

In order to start up friction compensation without adaptation, the adaptation must be deactivated.

Deactivate adaptation

⇒ MD 32510: FRICT_COMP_ADAPT_ENABLE[n] = 0

4. Determine compensation parameters

Friction compensation without adaptation is defined by the following parameters:

1. MD 32520: FRICT_COMP_CONST_MAX [n] friction compensation value (amplitude) in [mm/min]

2. MD 32540: FRICT_COMP_CONST_TIME [n] friction compensation time constant in [s]
These two parameters are changed until the circularity test produces minimum or no deviations from the programmed radius at the quadrant transitions (see the next 4 figures). The tests must be performed with different radii and velocities (typical values for the application of the machine).

**Start value**

A relatively low injection amplitude plus a time constant of a few position controller cycles should be entered as the start value when measuring commences.

**Example:**

MD 32520: \( \text{FRICT\_COMP\_CONST\_MAX} [n] = 10 \text{ (mm/min)} \)

MD 32540: \( \text{FRICT\_COMP\_TIME} [n] = 0.008 \text{ (8 ms)} \)

The effect of changing the parameters must be checked using the measured and plotted circles.

**Averaging**

If it is not possible to determine a common compensation time constant for the varying radii and velocities, then the average of the calculated time constants must be worked out.

**Good friction compensation setting**

When the friction compensation function is well set, quadrant transitions are no longer noticeable (see figure below).

![Figure 3-11 Quadrant transitions with correctly set friction compensation](image-url)
### Amplitude too low

When the injection amplitude setting is too low, radius deviations from the programmed radius are compensated inadequately at quadrant transitions during circularity testing (see figure below).

![Fig. 3-12 Amplitude too low](image)

### Amplitude too high

When the injection amplitude setting is too high, radius deviations at quadrant transitions are manifestly overcompensated at quadrant transitions (see figure below).

![Fig. 3-13 Amplitude too high](image)
2.5 Friction compensation (quadrant error compensation)

**Time constant too low**

When the compensation time constant settings are too low, radius deviations are compensated briefly at quadrant transitions during circularity testing, but are followed immediately again by greater radius deviations from the programmed radius (see figure below).

![Fig. 3-14 Compensation time constant too small](image)

**Time constant too high**

When the compensation time constant settings are too high, radius deviations are compensated at quadrant transitions during circularity testing (on condition that the optimum injection amplitude has already been calculated), but the deviation in the direction of the arc center increases significantly after quadrant transitions (see figure below).

![Fig. 3-15 Compensation time constant too large](image)
If, with the time constant and the constant injection amplitude determined, a
good result is achieved both in the circularity test and in positioning over the
whole working area (i.e. for all radii and velocities of relevance), curve adapta-
tion will not be necessary.

However, if the friction compensation turns out to be dependent on the accel-
eration, the adaptation characteristic must be calculated in second stage (see
stage 2: Friction compensation with adaptation).

Installation stage 2: Friction compensation with adaptation

Application

Whenever friction compensation depends on the acceleration and the required
results cannot be obtained with constant injection amplitude, adaptation must
be used.

In order to obtain optimum compensation over the whole of the working range of
the friction feedforward control where high demands are made on accuracy, the
acceleration dependency of the compensation value must be calculated. To
achieve this, the dependency must be measured at various points in the work-
ing range between acceleration zero and the maximum planned acceleration.
The adaptation characteristic derived from the measurement results is then en-
tered in the above machine data axis-specifically.

1. Determining the adaptation characteristic

   For different radii and velocities ... 
   1. ... it is necessary to determine the required injection amplitudes 
   2. ... it is necessary to check the compensatory effect of the injection
      amplitudes using the circularity test 
   3. ... it is necessary to log the optimum amplitudes.

   The adaptation characteristic (for example, see Fig. 3.8) is defined completely
   by determining the parameters specified in Section 2.5.2. However, many more
   measured values must be obtained for checking purposes. It must be ensured
   that there is a sufficiently large number of interpolation points for small radii at
   high speed. The size of the curves must be obtained by plotting.

2. Determining acceleration values

   During circular movement, the axial acceleration values are calculated using the
   radius r and the traversed velocity v according to the formula 
   \[ a = \frac{v^2}{r}. \]
   Using the feedrate override switch it is easy to vary the velocity and therefore
   axial acceleration value a.

   Acceleration values \(a_1\), \(a_2\) and \(a_3\) for the adaptation characteristic must be en-
tered in MD 32550: FRICT_COMP_ACCEL1 to MD 32570: FRICT_COMP_AC-
CEL3 in compliance with the condition \(a_1 < a_2 < a_3\). If the curve is wrongly para-
meterized, the alarm 26001 “Parameterization error for friction compensation” is
output.
2.5 Friction compensation (quadrant error compensation)

1. Calculation of acceleration
   The axial acceleration during the passage through zero of the speed for a
circular path is calculated using the formula $a = \frac{v^2}{r}$.
With the radius $r = 10$ mm and a circular velocity of $v = 1$ m/min
($=16.7$ mm/s) the acceleration is therefore $a = 27.8$ mm/s².

2. Input of the curve knee points
   The following accelerations were calculated to be the curve knee points:
   $a_1 = 1.1$ mm/s² ; $a_2 = 27.8$ mm/s² ; $a_3 = 695$ mm/s²
   The following values are therefore entered in the machine data in this order:
   
   | MD 32550: FRICT_COMP_ACCEL1 [n] | = 0.0011 [m/s²] |
   | MD 32560: FRICT_COMP_ACCEL2 [n] | = 0.0278 [m/s²] |
   | MD 32570: FRICT_COMP_ACCEL3 [n] | = 0.695 [m/s²] |

   For example, the following values were calculated for the injection amplitudes:
   
   | MD 32520: FRICT_COMP_CONST_MAX [n] | = 30 [mm/min] |
   | MD 32530: FRICT_COMP_CONST_MIN [n] | = 10 [mm/min] |

Note
If the results obtained at very low velocities are not satisfactory, then the computa-
tional resolution for linear positions MD 10200: INT_INCR_PER_MM or for
angular positions MD 10210: INT_INCR_PER_DEG must be increased.
See also MD 32580: FRICT_COMP_INC_FACTOR
(weighting factor of friction compensation value for short traversing move-
ments).
2.6 Neural quadrant error compensation

2.6.1 Fundamentals

Principle of QEC

As explained in Section 2.5, the purpose of quadrant error compensation (QEC) is to reduce contour errors occurring during reversal as the result of drift, backlash or torsion. Compensation is effected through prompt injection of an additional speed setpoint (see figure below).

In conventional QEC, the intensity of the compensation pulse can be set according to a characteristic as a function of the acceleration. This characteristic must be calculated and parameterized by a circularity test during start-up (see Fig. 3.8). The procedure for this is relatively complicated and requires some experience.

Advantages of QEC with neural network

On the SINUMERIK 840D with Software Version 2 or higher, the characteristic block that used to be manually parameterized can now be replaced by a neural network. This has the following advantages:

- Start-up has been simplified because the compensation characteristic no longer needs to be set manually by the start-up engineer but is determined automatically during a learning phase.

- The characteristic for a manually parameterized friction compensation is approximated by a polygon with 4 straight lines (see Fig. 3.8). For improved precision, the neural network can reproduce the real curve much better.

The resolution of the characteristic curve can be adapted to the precision requirements and a directional quality of the compensation amplitude can be considered.

In addition to the compensation amplitude, it is possible to adapt the decay time to the acceleration in special cases.

- The system permits simple automatic re-optimization on site at any time.
An essential requirement for implementing QEC with neural network is that the errors occurring on the workpiece at quadrant transitions are detected by the measuring system. This is only possible either with a direct measuring system, with an indirect measuring system with clear reactions of the load on the motor (i.e. rigid mechanics, little backlash) or with suitable compensation. With indirect measuring systems, any backlash that might occur must be compensated by backlash compensation.

QEC with neural network involves the following two phases:

- **Learning phase**
  During the learning phase, a certain pattern of behavior is memorized in the neural network. The relation between the input and output signals is learnt. The result is the learnt compensation characteristic that is stored in the non-volatile user memory. Activation and deactivation of the learning process is programmed in the NC part program using special high-level language commands.

- **Working phase**
  During the working phase, additional speed setpoint pulses are injected in accordance with the learnt characteristic. The stored characteristic does not change during this phase.

The learning phase can be executed for several (up to 4) axes at the same time. For further information about training the neural network, see Section 2.6.3.

The learning and working phases and the resulting neural QEC are purely axial. There is no mutual influence between the axes.

On completion of the learning phase, the calculated compensation data (characteristic values in user memory) including the network parameters (QEC system variables) must be saved in a file selected by the operator. As a standard, these files are called "AXn_QEC.INI".

These saved and learned compensation data can be loaded back directly to the user memory in the same way as part programs.

When the part program containing the tables is loaded, the compensation values are transferred to the NC user memory. The characteristic values become effective only after compensation has been enabled.

Characteristic values **cannot** be written when the compensation function is **active** (MD 32500: FRICT_COMP_ENABLE must be set to 0 and activated).

With QEC: The QEC must be enabled (and activated) by setting MD 32500: FRICT_COMP_ENABLE = 1 (QEC active).

As mentioned above, the neural network integrated in the control automatically adapts the optimum compensation data during the learning phase.

The axis involved must perform reversals with acceleration values constant section by section. Before activation of the learning phase, the parameters of the neural network (QEC system variables) must be pre-assigned in accordance with the requirements.
In order to simplify start-up as much as possible, NC programs are provided as reference examples.

As described in Section 2.6.4, the start-up engineer must first learn the characteristic for the axes using these reference examples and the recommended QEC parameter values and check the contour accuracy achieved using the circularity test (see Section 2.7). If the results do not meet the requirements, re-optimization must be performed changing the parameters appropriately (see Sections 2.6.2, 2.6.3 and 2.6.5) (i.e. relearning).

2.6.2 Parameterization of neural QEC

Machine data

The basic configuring data for the neural QEC are stored as machine data.

- MD 32490: FRICT_COMP_MODE
  Method of friction compensation (2 = neural QEC)
- MD 32500: FRICT_COMP_ENABLE
  Friction compensation active
- MD 32580: FRICT_COMP_INC_FACTOR
  Weighting factor for friction compensation value for short traversing blocks
- MD 38010: MM_QEC_MAX_POINTS
  Maximum number of compensation values for QEC with neural networks

With these machine data, the neural QEC is activated as soon as the memory space is reserved in the non-volatile RAM. The procedure and assignment is described in Section 2.6.4 “Start-up” or in Chapter 4.

All other data are set using system variables.

QEC system variables

The data for parameterizing the neural network are defined as system variables that can be written and read by an NC program. The following system variables are used for parameterization of the neural network:

- **$AA_QEC_COARSE_STEPS** “Coarse quantization of the characteristic”

  This parameter defined the coarse quantization of the input signal and is therefore the resolution of the characteristic. The larger the value that is selected, the higher the memory requirement and the greater the length of time required for the training phase. See the end of this section for more information.

  Value range: 1 to 1024; recommended value: 49

- **$AA_QEC_FINE_STEPS** “Fine quantization of the characteristic”

  This parameter defines the fine quantization of the input signal and is therefore the resolution of the characteristic. The larger the value that is selected, the higher the memory requirement.

  Value range: 1 to 16; recommended value: 8
Compensations (K3)

2.6 Neural quadrant error compensation

- **$AA_QEC_DIRECTIONAL**  
  “Directionality”
  This parameter defines whether the compensation is to be injected directionally or not. If activated, a separate characteristic is determined and stored for each acceleration direction. Because two characteristics are used, double the memory space must be reserved in the non-volatile user memory.
  Value range: TRUE/FALSE; recommended value: FALSE

- **$AA_QEC_LEARNING_RATE**  
  “Learning rate for the active learning phase”
  With the learning rate it is possible to determine how quickly the optimum characteristic is to be learnt in the active learning phase of the neural QEC. This value is a weighting factor with which it is possible to define to what extent the deviations affect the injection amplitude. With values greater than 100%, the characteristic is learnt more quickly but too high learning rate values (weighting factors) can cause instability (two-step response).
  A small learning rate is recommended for re-learning processes during normal operation (<50%) otherwise the characteristic is changed on every little disturbance when the speed passes through zero.
  Value range: > 0%; \leq 500%; recommended value: 50%

- **$AA_QEC_ACCEL_1 / _2 / _3**  
  “Acceleration limit values for the characteristic ranges 1 / 2 / 3”
  The acceleration characteristic is divided into three ranges. A different quantization of the acceleration stages applies to each range. In the low acceleration range, an especially high resolution is required for the characteristic in order to reproduce the widely varying compensation values there. For this reason, the input signals are quantized more finely, the smaller the acceleration is.
  Recommended values for
  - $AA_QEC_ACCEL_1 20 \text{ mm/s}^2$ (2% of $AA_QEC_ACCEL_3$)
  - $AA_QEC_ACCEL_2 600 \text{ mm/s}^2$ (60% of $AA_QEC_ACCEL_3$)
  - $AA_QEC_ACCEL_3 1000 \text{ mm/s}^2$ (maximum acceleration of the working range)
  The value of the parameter $AA_QEC_ACCEL_3$ must be entered as appropriate to the requirements; i.e. the neural network only works and learns optimally in this range. If a higher acceleration is detected than the parameterized working area, the injection amplitude that was determined during the defined maximum acceleration of the working area is used. At high accelerations, this injection value is relatively constant.
  The recommended values must only be changed if the compensation is insufficient in these acceleration ranges. For further information see Section 2.6.5.

- **$AA_QEC_TIME_1**  
  “Time constant for the neural QEC (decay time)”
  With this, the decay time of the compensation setpoint pulse is set if adaptation of the decay time is not used.
The optimum decay time must be ascertained manually using the circularity test at a working point in the mid acceleration range. The procedure is detailed in the section dealing with friction compensation (Section 2.5.3) (analogous to MD 32540: FRIC_COMP_TIME).

With the recommended value (15ms), it is possible to achieve good results.

Value range: ≥ 0; recommended value: 0.015s

If the decay time adaptation is active, then $AA_QEC_TIME_1$ determines the filter time constant in the center of the operating range (i.e. with 0.5 * $AA_QEC_ACCEL_3$).

- **$AA_QEC_TIME_2**
  “Compensation time constant for adaptation of the decay time of the correction values”

At a value of zero of less than or equal to $AA_QEC_TIME_1$, no adaptation is performed.

The decay time is usually constant over the entire working range. In rare cases however, it can be advantageous to raise the decay time in the very small acceleration range, or to lower it at high accelerations. For further information see Section 2.6.5.

Value range: ≥ 0; recommended value: 0.015 s (identical to $AA_QEC_TIME_1$)

- **$AA_QEC_MEAS_TIME_1 / _2 / _3**
  “Measurement duration for determining the error criterion in the acceleration range 1 / 2 / 3”

The measuring time is started, as soon as the criterion for injection of the compensation value is fulfilled (i.e. the set speed changes sign). The end of the measuring item is defined by the set parameter values.

Different measuring times are required for each characteristic range.

Recommended values for
- $AA_QEC_MEAS_TIME_1$: 0.090 s (= 6 * $AA_QEC_TIME_1$)
- $AA_QEC_MEAS_TIME_2$: 0.045 s (= 3 * $AA_QEC_TIME_1$)
- $AA_QEC_MEAS_TIME_3$: 0.030 s (= 2 * $AA_QEC_TIME_1$)

The recommended values must only be changed if the compensation is insufficient in these acceleration ranges or if $AA_QEC_TIME_1$ is changed. For further information see Section 2.6.5.

Transfer of parameters

The QEC system variables are stored in the non-volatile user memory after the NC program is started where they remain unchanged until the memory is erased or re-formatted or until a new learning or relearning process takes place or until they are written by the NC program.
Before the learning cycle is called, all system variables must be assigned valid values for the learning process. For example, this can be done in a subprogram. After this NC program has run and a reset has been performed, the QEC data are active.

**Characteristic data**

The characteristic data determined during the learning process are stored as system variables in the user memory reserved for this purpose.

Format:  \$AA_QEC[n]  
Range of n: 0 to 1024

These values write the learned characteristic in internal formats and must therefore **not be changed**!

**Quantization of characteristic**

The quantization, and thus the resolution, of the characteristic is defined via the two quantities **fine quantization** (\$AA_QEC_FINE_STEPS) and **coarse quantization** (\$AA_QEC_COARSE_STEPS). The finer the resolution, the higher the memory requirement and the longer the duration time required for the learning phase.

The number of memory locations required and the total number of quantization intervals is calculated by the formula:

\[
\text{Number of memory locations} = \$AA_QEC_FINE_STEPS \times (\$AA_QEC_COARSE_STEPS+1)
\]

Up to 1025 memory locations per axis can be reserved. In this way, a sufficiently high resolution is achieved for high precision requirements.

The following 3 figures illustrate the meaning of the characteristic values for coarse and fine quantization, and their effect on the teach-in period, as a function of the parameter “Detailed learning active y/n”. Three cases are distinguished for better understanding.

Case 1: Coarse quantization > 1; fine quantization = 1  
(special case; usually the fine quantization is in the region of eight):

In this case, the interpolation points of the characteristic are determined solely by coarse quantization (see figure below).

![Fig. 3-17 Coarse quantization of characteristic](image-url)
2.6 Neural quadrant error compensation

Case 2: Coarse quantization > 1; fine quantization > 1; “Detailed learning” is deactivated (this setting is the default):

In this case, discrete linear interpolation is used for fine quantization between the interpolation points of the coarse quantization.

The learning duration is identical with 1 because learning only occurs at the interpolation points of the coarse quantization.

The effect of fine quantization on a section of characteristic within a coarse quantization process is shown in the figure below (see also Section A in figure above).

![Diagram](attachment:image.png)

**Fig. 3-18** Effect of fine quantization with “Detailed learning” inactive

Case 3: Coarse quantization > 1; fine quantization > 1; “Detailed learning” is activated (its use is only recommended for very high precision requirements):

With “Detailed learning”, learning occurs both at the interpolation points of the coarse quantization and of the fine quantization.

The learning duration is therefore much longer.

The figure below shows a severely fluctuating characteristic curve on which the effect of selecting and deselecting the “Detailed learning” function is clear.
2.6 Neural quadrant error compensation

Fig. 3-19 Effect of fine quantization with "Detailed learning" active
2.6.3 Learning the neural network

**Learning process sequence**
A certain type of response is impressed upon the neural network during the learning phase. The relation between the input and output signals is learnt.

The learning process is controlled entirely by NC programs and is divided into the following areas:

1. Preset the QEC system variables for the learning process
2. Activate QEC system variables (by starting the NC program)
3. Parameterize the learning cycle
4. Start the learning cycle

The result is the learnt compensation characteristic that is stored in the non-volatile user memory.

The results achieved must be checked using the circularity test (Section 2.7).

**Reference NC programs**
In order to ease the task of the start-up engineer in starting up the QEC with neural networks, NC programs containing specimen routines for learning movements and assignments of QEC system variables (recommended values) are available.

These are the following reference NC programs:

- **QECLRNP.SP**E Learning with POLY standards  
  (Option “POLY” necessary)
- **QECLRNC.SP**E Learning with circles
- **QECDAT.MP**F Reference NC program for assigning system variables and for parameterization of the learning cycle
- **QECSTART.MP**F Reference NC program that calls the learning cycle

These NC programs are contained on the diskette of the basic PLC program for the SINUMERIK 840 D.

Implementing the learning process solely via NC programs has the following advantages:

- Learning can be fully automatic without operator intervention. This is advantageous for series start-ups if the optimum learning parameters for a machine type have been found and it only remains to determined or retrained the characteristic for each individual machine.
- Learning can be executed for several axes (up to 4) simultaneously. This reduces the learning phase for the machine considerably.
- The traverse movements can easily be adapted to special requirements.
- Start-up of the neural QEC is possible even where a simple MMC is used (e.g. MMC100) (exception: a circularity test on the MMC is only possible with MMC101–103; otherwise use an installation tool).
The axis traversing motions that must be executed to learn a specific response are generated by an NC program. Each learning motion of the sample learning cycle comprises a group of NC blocks with parabolic movements (ensuring that the axis traverses at the most constant possible setpoint speed after the zero crossing; see figure below) in which the axes oscillate at constant acceleration in each program section. The acceleration is decreased from group to group. In the figure below, NC blocks 2 to 3, 5 to 6 and 8 to 9 each form a group; the transitional movements to lower acceleration rates are programmed in blocks 1, 4, 7 and 10.

Note
So that the learning parameters act as preset, the feedrate override switch must be set to 100% during the learning phase.

Before a learning cycle is called, all QEC system variables must be set to the values required for the learning process. The values recommended in the reference NC program must be checked and changed if necessary (see Section 2.6.2).

The actual learning process of the neural network is then activated in the reference NC program. This is done using the following high-level language command:

```
QECLRNON(axis name 1, ... 4)  Activate learning (for the specified axes)
```

Only during this phase are the characteristics changed.

After the learning motions of the required axes have been completed, the learning process is deactivated for all axes. This is done with the high-level language command:

```
QECLRNOF  Deactivate learning (simultaneously for all axes)
```

After power-on reset, end of program (M02/M30) or operator panel reset, the learning is also deactivated.
The current “Learning on / off” status is displayed in the service display “Axes” with “QEC learning active” (1 = active; 0 = inactive).

**Learning cycle call** Once learning has been activated, the reference NC program calls the learning cycle by means of the following input parameters:

- **Number of axes** to which learning is to apply (up to four).
  Requirement: If more than one axis is to learn at the same time, all QEC system variables of the axes involved must have the same values. These values are monitored and an error message is output if they are not equal.

- **Names of the learning axes**

- **Initial number** (same for all axes)
  Value always 0 (setpoint branch)

- **Learning mode** (initial learning = 0; relearning = 1)
  0: Initial learning active. All values of the network are preset to 0 before learning.
  1: Relearning active: Learning continues with the values already learnt in the defined step width.

- **Detailed learning active** yes/no (TRUE/FALSE)
  FALSE: “Detailed learning” is not active. The characteristic is therefore learnt in the step width of the coarse quantization of the acceleration.
  TRUE: “Detailed learning” is active. The characteristic is therefore learnt in the step width of the fine quantization of the acceleration, i.e. with fine quantization of 10 steps per coarse step, determination of the characteristic takes ten times longer. This parameter must therefore only be used for extremely high precision requirements.

**Note**
If “Detailed learning” is selected, the number of learning passes can and must be reduced in order to reduce the learning duration (recommended range: between 1 and 5).
2.6 Neural quadrant error compensation

- **Number of learning passes**
  Default value = 15; range > 0

  The effect of this parameter depends on whether “Detailed learning active” is set or not.

  a) Detailed learning not active (= FALSE):
  The number of test motions (back and forth) is defined for each acceleration stage. The higher the number, the more accurate learning is, but the longer learning takes.

  With directional compensation ($AA_{QEC\_DIRECTION} = TRUE$), the parameterized number of test movements for every direction is generated.

  b) Detailed learning active (= TRUE):
  In this way, the number of complete passes from maximum to minimum acceleration and vice versa is activated with the fine step width.
  In other words, with a value of 1, all acceleration steps are passed through starting with the maximum value. For every acceleration stage, two test movements are generated if there is no directional compensation ($AA_{QEC\_DIRECTION} = FALSE$), otherwise four test movements are performed per acceleration stage.

  A reduction of the “Number of learning passes” can be made if data blocks for the machine type already exist (series machines) and these are to be used as a basis for further optimization.

- **Section-by-section learning active** yes/no (TRUE/FALSE)
  “Section-by-section learning” in certain acceleration ranges is especially interesting for “Detailed learning” e.g. in technologically important ranges of the machine. By defining the ranges appropriately it is possible to reduce the learning duration.

  Default = FALSE

- **Range boundaries for “Section-by-section learning”** (minimum acceleration, maximum acceleration); only relevant for “Section-by-section learning active”.

  Default value = 0; format: mm/s²

- **Time taken for one test motion** (to and fro)

  Default value = 0.5; format: s (seconds)
  (corresponds to a frequency of 2 Hz)

**Requirement**

In the learning phase, the neural QEC requires a speed feedforward control (MD 32620; FFW_MODE=1; FFWON), but no jerk limitation (BRISK). The feedforward control must therefore be correctly parameterized and optimized.

When the learning process is started a check is made to see whether the speed feedforward control is activated. If not, the learning process is cancelled and an error message is generated.
2.6.4  Start-up of neural QEC

This describes start-up of QEC with neural networks. As we have already mentioned, the compensation characteristics during the learning phase are determined automatically.

The axis involved must perform reversals with acceleration values constant section by section. The QEC system variables for parameterization of the neural network must also be preset to meet the requirements.

To simplify start-up as much as possible, NC programs are provided to serve as reference examples (see Section 2.6.3).

In the learning process, a distinction is made between “initial learning” (especially for first start-up) and “relearning” (especially for re-optimization of characteristics already learnt). The procedures of “initial learning” and “relearning” are described below.

If the compensation characteristics for the machine are to be learnt for the first time, we recommend use of the reference NC programs specified in Section 2.6.3.

“Initial learning” process

1. a) Activate QEC with neural networks for the required axes:
   MD 32490: FRICT_COMP_MODE = 2
   Note: QEC with neural networks is an option.
   b) Reserve memory space for the compensation points
   MD 38010: MM_QEC_MAX_POINTS
   If the required number is not yet known, a generous amount of memory must be reserved initially (see also item 12).
   c) Parameterize and optimize the speed feedforward control (required for the learning phase)
   d) Perform a hardware reset (because of the re-allocation of the non-volatile user memory).

2. Activate the QEC system variables:
   Adapt the reference NC program QECDAT.MPF for assigning the QEC system variables for all axes concerned (if necessary use the recommended values) and start the NC program. If error messages are output, correct the values and restart the NC program.

3. Create the NC program that moves the machine axes to the required positions and parameterizes and calls the reference learning cycle QECLRN.SPF (as in the example program QECSTART.MPF). The feedrate override switch must be set to 100% of the learning phase so that the parameters can take effect in accordance with the defaults.

4. Activate the learning phase by starting this NC program.
   The compensation characteristic is learnt for all the parameterized axes simultaneously. The learning duration depends on the specified learning parameters. If default values are used, it can take several minutes.
   The status of the axes concerned can be observed in the service display “axis” in the display “QEC learning active”.

General notes

This describes start-up of QEC with neural networks. As we have already mentioned, the compensation characteristics during the learning phase are determined automatically.

The axis involved must perform reversals with acceleration values constant section by section. The QEC system variables for parameterization of the neural network must also be preset to meet the requirements.

To simplify start-up as much as possible, NC programs are provided to serve as reference examples (see Section 2.6.3).

In the learning process, a distinction is made between “initial learning” (especially for first start-up) and “relearning” (especially for re-optimization of characteristics already learnt). The procedures of “initial learning” and “relearning” are described below.

If the compensation characteristics for the machine are to be learnt for the first time, we recommend use of the reference NC programs specified in Section 2.6.3.
5. Activation of the injection of the compensation values for the required axes: 
   MD 32500: FRICT_COMP_ENABLE = 1.

6. Parameterize the trace for the circularity test in the menu "Circularity test measurement" (with MMC101–103 or installation tool). 
   Parameter values for the reference NC program: 
   Radius[mm]: 
   Feedrate[mm/min]. 
   After this, enable the measuring function with the vertical softkey “start”.

7. Start the NC program with the test motion (circle). 
   The position actual values are recorded during the circular movement and stored in the passive file system. After termination of data recording, the recorded contour is displayed as a diagram.

8. Check the quadrant transitions for the contour recorded.

9. Depending on the result, repeat items 2, 4, 7, 8 and 9 if necessary. It might be necessary to change certain QEC system variables first (see also Section 2.6.3).

10. The compensation characteristics must be saved as soon as the contour precision meets the requirements (see Section 2.6.3).

11. If necessary, the memory area previously reserved for the compensation values can be reduced to the memory actually required.

   **Caution:** When the setting in MD 38010: MM_QEC_MAX_POINTS is altered, the non-volatile user memory is automatically re-allocated on system power-on. All the user data in the non-volatile user memory are lost. These data must therefore be backed up first. After power-on of the control, the backed up characteristics must be loaded again.

---

### “Relearning” process sequence

“Relearning” –> cycle parameter “Learning mode” = 1

The “Relearning” function allows characteristics that have already been learned to be re-optimized in a simple, automatic process. The values already in the user memory are taken as the basis.

The reference NC programs adapted to the machine (e.g. from “initial learning”) must be used in the learning phase for “relearning”. Generally, the previous values of the QEC system variables can still be used. Before the learning cycle is called, the parameter “learning mode” must be set to 1 (meaning “relearning”). It might also be used to reduce the “number of training passes”.
Sequence of operations for “Relearning”

The sequence of operations involved in the “Relearning” process is described below.

1. If characteristic values have not yet been stored in the user memory (RAM) (e.g. start-up of a series machine), the pre-optimized data block must be loaded (see Section 2.6.1).

2. Adapt the NC program that moves the machine axes to the required positions and parameterizes and calls the learning cycle. The parameters for the learning cycle (e.g. QECLRN.SPF) might have to be changed for “relearning”.
   - Set “learning mode” = 1
   - Reduce the “number of learning passes” if necessary (e.g. to 5)
   - Activate “section-by-section learning” if necessary and define the associated range boundaries

3. Activate the learning phase by starting this NC program. The compensation characteristic is learnt for all the parameterized axes simultaneously.

4. Parameterize the trace for the circularity test in the menu “Circularity test measurement” (with MMC101–103 or installation tool). After this, enable the measuring function with the vertical softkey “start”.

5. Start the NC program with the test motion for circularity test. The position actual values are recorded during the circular movement and stored in the passive file system. After termination of data recording, the recorded contour is displayed on the MMC.

6. Check the quadrant transitions for the contour recorded.

7. Depending on the result, repeat items 3, 4, 5 and 6 if necessary. It might be necessary to change certain QEC system variables first (see also Section 2.6.5).

8. The compensation characteristics must be saved as soon as the contour precision meets requirements (see Section 2.6.1).
2.6.5 Further optimization and intervention options

**Optimization options**

In cases where the results of the circularity test do not meet the required accuracy standards, the system can be further improved by selective changes to QEC system variables. Several ways of optimizing the neural QEC are explained here.

**Alteration of coarse and fine quantization**

As described in previous sections, input variables are quantized by means of the "Coarse quantization" and "Fine quantization" values.

A high value for the fine quantization causes a "similar" output signal to be obtained for adjacent intervals of the input signal, allowing, for example, measuring errors which occur only at a particular acceleration rate to be identified (see Fig. 3.16).

With a low fine quantization, highly fluctuating characteristics are reproduced better.

For the neural friction compensation, it is necessary to make use of the largest error tolerance by setting a high fine quantization ($AA_{QEC\_FINE\_STEPS}$ in the region of 5 to 10).

**Direction-dependent compensation**

Direction-dependent friction compensation must be used in cases where compensation is not applied equally on opposing quadrants when compensation values are being injected independently of direction (see figure below).

The directional injection is activated via the system variable $AA_{QEC\_DIRECTIONAL} = TRUE$.

Here, the following aspects must be observed:

- Since a characteristic is learned and stored for every direction of acceleration, double the memory space is required in the non-volatile user memory. MD 38010: MM$_{QEC\_MAX\_POINTS}$ must be set accordingly.
- The number of learning passes must be raised because only every second passage occurs at the same location.
- If the characteristic resolution is the same, start-up takes longer.
2.6 Neural quadrant error compensation

The acceleration characteristic is subdivided into three ranges. In the low acceleration range, an especially high resolution is required for the characteristic in order to reproduce the widely varying compensation values there. Therefore, the lower the acceleration rate, the finer the quantization of the input quantity (see figure below).

In the high acceleration range, there are only small changes in the compensation values so that a small resolution is perfectly sufficient.

The percentage settings recommended in Section 2.6.2 for $AA_{QEC\_ACCEL\_1}$ (2% of $AA_{QEC\_ACCEL\_3}$) and for $AA_{QEC\_ACCEL\_2}$ (60% of $AA_{QEC\_ACCEL\_3}$) are based on empirical values measured on machines with a maximum acceleration rate (= operating range) of up to approx. 1 m/s².

If the working range is significantly reduced, then the limit values for $a_1$ and $a_2$ must be set somewhat higher as a percentage of $a_3$. However, $AA_{QEC\_ACCEL\_1}$ must not exceed the range of approx. 5% of the maximum acceleration. Useful boundaries for $AA_{QEC\_ACCEL\_2}$ are approx. the values 40% to 75% of the maximum acceleration.
Adaptation of decay time

In special cases, it is possible to adapt the decay time of the compensation set-point pulse in addition to the compensation amplitude.

If, for example, the circularity test reveals that in the low acceleration range \(a_1\) the quadrant transitions yield good compensation results but that radius deviations occur again immediately after this, it is possible to achieve an improvement by adapting the decay time.

The time constant without adaptation \(\$AA_QEC\_TIME\_1\) is only valid in the mid acceleration range (50%).

The adaptation of the decay time for the compensation setpoint impulse according to the characteristic shown in the figure below is parameterized with system variable \$AA_QEC\_TIME\_2\) (for acceleration = 0). The adaptation is formed by these two points according to an \(e^{-x}\) function (see figure below).

The adaptation is performed under the following condition:
\[\$AA_QEC\_TIME\_2 > \$AA_QEC\_TIME\_1\]

![Fig. 3-23 Adaptation of the decay time](image)

Alteration of error measuring time

During the learning phase for the neural network, the error measuring time determines the time window within which contour errors are monitored after a zero-speed passage.

Experience has shown that the error measuring time to be used for average acceleration rates (approx. 2 to 50mm/s²) corresponds to three times the value of the decay time \(\$AA_QEC\_MEAS\_TIME\_2 = 3 \times \$AA_QEC\_TIME\_1\).

In the very low and high acceleration ranges, the error measuring time must be adapted. This is done automatically according to the characteristic in the figure below. The error measurement duration for small accelerations is set to six times the value of the decay time \(\$AA_QEC\_MEAS\_TIME\_1 = 6 \times \$AA_QEC\_TIME\_1\); double the decay time \(\$AA_QEC\_MEAS\_TIME\_3 = 2 \times \$AA_QEC\_TIME\_1\) is taken as the error measurement time for larger accelerations.
In special cases, it might be necessary to reparameterize the error measuring times:

- Setting very extreme values for the compensation time constant of the QEC. Experience has shown that error measuring times of less than 10 ms and greater than 200 ms are not useful.

- Parameterization of the error measuring times with adaptation of the decay time of the compensation value.

If the adaptation of the decay time of the compensation value is active (see above), the following rule of thumb is applicable to the parameterization of the error measuring time for acceleration range 1:

\[
\text{AA_QEC_MEAS_TIME}_1 = 3 \times \text{AA_QEC_TIME}_2
\]

Example:
Decay time (\(\text{AA_QEC_TIME}_1\)) = 10 ms
Adaptation of the decay time (\(\text{AA_QEC_TIME}_2\)) = 30 ms
Following the rule of thumb given above, the error measuring time for acceleration range 1 is therefore:

\[
\text{AA_QEC_MEAS_TIME}_1 = 3 \times 30 \text{ ms} = 90 \text{ ms}
\]

Without adaptation of the decay time, it would only be

\[
\text{AA_QEC_MEAS_TIME}_1 = 6 \times 10 \text{ ms} = 60 \text{ ms}
\]

**Overcompensation with short traversing motions**

Practical experience has shown that the optimum friction compensation value calculated from the circularity test may result in overcompensation on the relevant axis if it executes very short axial positioning movements (e.g. on infeeds in the \(\mu\)m range).

To improve accuracy in such cases too, it is possible to reduce the compensation amplitude for short traversing motions.
Compensations (K3) 04.95

2.6 Neural quadrant error compensation

This weighting factor programmed in MD 32580: FRICT_CMP_INC_FACTOR automatically takes effect when friction compensation is activated (conventional QEC or QEC with neural networks) acting on all positioning movements that are made within an interpolation cycle of the control.

The input range is between 0 and 100% of the calculated compensation value.

Control of learning process duration

As described in previous sections, the duration of the learning process is dependent on several parameters. It is mainly dependent on the following values:

- Coarse quantization ($AA_QEC_COARSE_STEPS)
- Measuring time for determining the error criterion ($AA_QEC_MEAS_TIME_1 up to $AA_QEC_MEAS_TIME_3)
- Number of learning passes
- Detailed learning active [yes/no]?
- Fine quantization ($AA_QEC_FINE_STEPS) (only if “detailed learning = yes” is selected)
- Directional compensation active [yes/no]? ($AA_QEC_DIRECTIONAL)
- Duration of reversing movement

The setting “Detailed learning active = yes” causes a significant increase in the time required for learning. It must therefore only be used where precision requirements are high. It is necessary to check whether these requirements only apply to certain acceleration ranges. If so, detailed learning only needs to be performed section by section (see “Section-by-section learning y/n?”). The number of learning passes must be reduced in any case.

If the reference NC programs mentioned above are used with the recommended parameter values, the following times have been determined for the learning process time:

- Detailed learning not active: approx. 6.5 min
- Detailed learning active: approx. 13 min
2.6.6 Quick start-up

Preparation for “Learning”

1. Determining the optimum friction compensation time constant (MD 32540 FRIC_COMP_TIME) with conventional friction compensation.

2. Enter the following machine data without POWER ON:

<table>
<thead>
<tr>
<th>Machine data</th>

</tr>
</tbody>
</table>

*) t_pos, ... Position control cycle (=basic system cycle * factor for position control cycle), n_setSm, ... speed setpoint smoothing (MD 1500 to 1521)

3. Owing to re-allocation of memory (MD 38010), save the machine data with MMC 100:
   “Services” “Data off” “Start-up data, NCK data” and if programmed, “LEC, measuring system error, sag and angularity error compensation tables” via PCIN.
   Execute a Power ON Reset and then read in the saved data with PCIN and “Data IN” (= series start-up).

MMC 102:
   Save “Series startup” and if programmed, “LEC, measuring system error, sag and angularity error compensation tables”.
   Execute a Power ON Reset and then read in the “Start-up” archive (saved data are loaded again).
4. Copy the programs supplied on disk “MMC 100 TOOLBOX” into the NC (with archive!)
   QECDAT.MPF
   QECSTART.MPF
   QECLRNP.SPF ("Polynomial" learning program) or QECLRNC.SPF ("Circle" learning program) is stored as QECLRN.SPF on the NC!
   With geometry axes, it is preferable to use the Circle learning program; for all other axes the Polynomial learning program only.

5. Adapt the following programs:
   – In the part program QECDAT
     if req. adapt friction compensation time constant (see Point 1)
     N1340  $AA_QEC_TIME_1[outNo,axNo] = 0.xxx
     N1040 def int numAxes = ..... Enter the number of axes that are to learn.
     N1150 axisName[0] = ...... Enter axis name of 1st axis.
     N1160 axisName[1] = ...... Enter axis name of 1st axis.
     N1180 axisName[3] = ...... Enter axis name of 1st axis.
     (AX1 .. AX8 or the machine or channel axis name can be used as an axis name for the “Circle” learning program. With “Polynomial” learning program, however, only the channel axis name)
   – In the part program QECSTART
     N1080 def int numAxes = ..... Enter the number of axes that are to learn.
     N1310 axisName[0] = ...... Enter axis name of 1st axis.
     N1320 axisName[1] = ...... Enter axis name of 1st axis.
     N1330 axisName[2] = ...... Enter axis name of 1st axis.
     N1340 axisName[3] = ...... Enter axis name of 1st axis.
     (AX1 .. AX8 or the machine or channel axis name can be used as an axis name for the “Circle” learning program. In contrast, only the channel axis name may be used for the “Polynomial" learning program).

**Executing “Learning” process**

Start the following programs

- Select and start QECDAT. System variables are assigned.
- Select QECSTART, override 100% and start.

The learning program runs for about 15 minutes involving approximately 30 cm traversing motions. If the message “REORG not possible” is displayed, it can be ignored. The message is displayed for about 10 seconds. It then disappears and the learning process continues with traversing motions.

**Activate QEC**

<table>
<thead>
<tr>
<th>Machine data</th>
<th>Default</th>
<th>Change to</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MD 32500</td>
<td>0</td>
<td>1</td>
<td>Switch on “Friction compensation active”</td>
</tr>
<tr>
<td>FRIC_COMP_ENABLE</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**“Circularity test”**

Use the “Circularity test” to check the result!
Save compensation data

Save the compensation data (QEC data are not saved with “SERIES START-UP”; can be selected in SW 4 and higher):

MMC 100:
Save with PCIN under SERVICES Data\Circle error compensation\All

MMC 102:
Save the file under SERVICES NCK \ NC Active Data \ Quadrant Error Co \ Quadrant error comp-complete.ini. This file contains all compensation values.

Note: Change the “displayed name length” to “20” in SERVICES “System settings” “for display” to ensure that the whole name is visible.
2.7 Circularity test

Function

One of the purposes of the circularity test is to check the contour accuracy obtained by the friction compensation function (conventional or neural QEC). It works by measuring the actual positions during a circular movement and displaying the deviations from the programmed radius as a diagram (especially at the quadrant transitions).

Procedure

The circular contour for the relevant axes is specified by an NC program. To simplify the circularity test as much as possible for the start-up engineer, an NC program is provided as a reference example for the circularity test motion (file QECTEST.MPF on the diskette with the basic PLC program). The start-up engineer must adapt this NC program to his application.

Several measurements must be made during the circularity test with different acceleration values to ascertain whether the learnt compensation characteristic (for neural QEC) or the defined compensation values (for conventional QEC) meet the requirements.

The circular movement can easily be made with different accelerations if you change the feedrate using the feedrate override switch without changing circular contour. The real feedrate must be taken into account in the measurement in the input field "feedrate".

The circle radius chosen must be typical of machining operations on the machine (e.g. radius in the range 10 to 200 mm).

For the duration of the circular movement, the position actual values of the axes are recorded and stored in a "trace" in the passive file system. The circularity test is therefore purely a measuring function.

Parameterization of circularity test

The axis names or axis numbers with which the circle is to be traversed and for which the position actual values are to be recorded are selected in this menu. No check is made to ascertain whether the selected axes correspond to those programmed in the NC part program.

The parameter settings in the input fields "Radius" and "Feed" must correspond to the values from the part program that controls the circular motion of the axes, taking account of the feed override switch setting. No check is made to see whether the values in the part program (including feedrate override) and the input values match.

The "Measuring time" display field shows the measuring time calculated from the "Radius" and "Feed" values for recording the position actual values during the circular movement.

If only parts of the circle can be represented (i.e. measuring time too short) the measuring time can be increased in the menu by reducing the feed value. This also applies if the circularity test is started from the stationary condition.
Mode of representation

The following parameter assignments for programming the mode of representation of measurement results can also be made:

- Display based on mean radius
- Display based on programmed radius
- Scaling of the diagram axes

If the measuring time calculated exceeds the time range that can be displayed from the trace buffers (maximum measuring time = position control cycle frequency * 2048), a coarser sampling rate is used for recording (n * position control cycle frequency), so that a complete circle can be displayed.

Start measurement

The operator must use an NC Start to start the part program in which the circular motion for the selected axes is stored (AUTOMATIC or MDA operating mode).

The measuring function is started with the vertical softkey Start.

The user can choose the operating sequence (NC start of the part program and starting measurement) to suit the application.

As soon as the circularity test is active for the specified axes, the message "Active" is output in the "Status" display field.
Stop measurement

The measurement can be interrupted at any time by means of softkey Stop. Any measurements that have not been fully recorded at that moment are displayed as completely as possible under softkey Display. There are no monitoring functions to check this.

For direct access to the required control parameters, the softkeys Axis-specific MD, FDD-MD and MSD-MD are provided. The required axis can be selected with the vertical softkeys Axis+ and Axis–.

When you press the softkey Service Axis the “Service axis” display is shown. This cyclically displays the following service data for start-up of friction compensation:

- QEC learning active yes/no?
- Current position and speed actual values

Display

When the softkey Display is selected, the screen switches over to graphic representation of the recorded circle diagram.

![Circularity test display](image)

Fig. 3-26 Circularity test display menu

This display shows the measured progression of both position actual values as a circle with the set resolution.

The programmed radius, the programmed feedrate and the resulting measuring time are also displayed for documentation purposes (for subsequent storage of the measured circularity characteristic in a file).

The user can input a finer scaling for the diagram axes in the input field Resolution, to emphasize the quadrant transitions for example. To redisplay the diagram after having changed the resolution, press the softkey Display.
File functions

The displayed measurement results and the parameter settings can be stored as a file on the MMC by selection of softkey **File functions**.

Printer settings

The basic display for selecting a printer (Fig. 10-15) can be called by means of softkeys **MMC \ Printer selection**.

The toggle key is used to define whether the displayed graphic is to be output directly on the printer or transferred to a bit map file after softkey **Print graph** is selected.

![Basic display for printer selection](image)

Fig. 3-27 Basic display for printer selection

Direct output on printer

The printer must be set up under MS-WINDOWS.

“Output on printer” is set in the selection field.

After selection of the softkey labeled **Print graph**, the displayed graph is output on the connected printer.

Output in bitmap file

The graphic is stored in a bitmap file (*.bmp).

“Output as bitmap file” is chosen in the printer settings selection field.

When the softkey labeled **Print graph** is selected, the screen form for assigning a file name appears in the “Circularity test display”. A new file name can be entered or an existing file name selected for overwriting in the drop-down list.

Softkey **Ok** is selected to store the file.

Softkey **Abort** is selected to return to the current graphic display.
2.7 Circularity test

2.7.1 Neural quadrant error compensation, quick start-up

Quick start-up “Neural Quadrant Error Compensation” with parabolic/circular movements on MMC 102/103/MMC 100

Preparation for “Learning” The friction compensation time constant (MD 32540 FRIC_COMP_TIME) is calculated first by means of conventional friction compensation.

Table 2-2 Enter the following machine data without Power On

*) \( t_{\text{pos.}} \) ... Position control cycle (=basic system cycle \( \times \) factor for position control cycle), \( n_{\text{setSm.}} \) ... speed setpoint filters (MD 1500 ... 1521)

Owing to re-allocation of memory (MD 38010), save the machine data with:

**MMC 100:** Save “Services”, “Data OUT”, “Start-up data, NCK data” and, if programmed, measuring system error and sag/angularity compensation tables via PCIN, execute a Power On-Reset and then read in the saved data with PCIN and “Data IN” (=series machine start-up).

**MMC 102/103:** Save “SERIES START-UP” and, if programmed, measuring system error and sag/angularity compensation tables, execute Power On-Reset and read in “Start-up” archive (saved data are reloaded).

**Copy the programs supplied on diskette “MMC 100 TOOLBOX” into the NC (with archive!)

QECDAT.MPF
QECSTART.MPF
QECLERNP.SPF ("Polynomial" learning program) or QECLRNC.SPF ("Circle" learning program) is stored as QECLRN.SPF on the NC!

**Adapt the following programs:**

- **In part program QECDAT**
  
  N1040 def int numAxes=... Enter the number of axes to be learned
  
  N1150 axisName[0] Enter axis name of 1st axis.
  
  N1160 axisName[1] Enter axis name of 1st axis.
  
  
  N1180 axisName[3] Enter axis name of 1st axis.
  
  (AX1 .. AX8 or the machine or channel axis name can be used as an axis name for the "Circle" learning program. In contrast, only the channel axis name may be used for the "Polynomial" learning program).

- **In part program QECSTART**
  
  N1080 def int numAxes=... Enter the number of axes to be learned
  
  N1310 axisName[0] Enter axis name of 1st axis.
  
  N1320 axisName[1] Enter axis name of 1st axis.
  
  N1330 axisName[2] Enter axis name of 1st axis.
  
  N1340 axisName[3] Enter axis name of 1st axis.
  
  (AX1 .. AX8 or the machine or channel axis name can be used as an axis name for the "Circle" learning program. In contrast, only the channel axis name may be used for the "Polynomial" learning program).

**Execute LEARN process**

Select and start QECDAT

System variables are assigned.

Select QECSTART: 100% override and start

The learning program runs for about 15 minutes involving approximately 30 cm traversing motions. The message “REORG not possible” can be ignored if it occurs. The message is displayed for about 10 seconds. It then disappears and the learning process continues with traversing motions.
Active QEC

<table>
<thead>
<tr>
<th>Machine data</th>
<th>Default</th>
<th>Change to</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MD 32500 FRIC_COMP_ENABLE</td>
<td>0</td>
<td>1</td>
<td>Switch on &quot;Friction compensation active&quot;</td>
</tr>
</tbody>
</table>

Use the “Circularity test” to check the result!

Save compensation data (QEC data are not included in back-up with “SERIES START-UP”):

MMC 100: Save with PCIN under SERVICES\Data\Circle error compensation\All.

MMC 102/103: Save the file under SERVICES\NCK\NC Active Data\Quadrant Error Co\Quadrant error comp-complete.ini. This file contains all compensation values.

Note

Change the “displayed name length” to “20” in SERVICES “System settings” “for display” to ensure that the whole name is visible.
2.8 Drift compensation (for SINUMERIK FM-NC only)

Drift

As a result of the temperature-dependent drift in analog components, analog speed control loops must be driven by a low speed setpoint other than zero in order to reach standstill. The position controller can only generate this speed setpoint if a small following error builds up at its input even at zero velocity. The axis/spindle therefore slowly moves from its set position until the speed setpoint has become so large because of the following error that it is equivalent to the temperature drift.

Compensation

To avoid this static error, a small additional speed setpoint is injected. This comprises the following components (see figure below):

1. Basic drift value (MD 36720: DRIFT_VALUE)
   The value set in MD 36720: DRIFT_VALUE is always added to the speed setpoint. The basic drift value is always active. It is input as a percentage of the maximum manipulated variable.

2. Automatic drift compensation (MD 36700: DRIFT_ENABLE)
   With machine data MD 36700: DRIFT_ENABLE = 1 (automatic drift compensation) it is possible to active automatic drift compensation on position-controlled axes.
   The control determines the additional drift value still required to reduce the following error to zero (compensation criterion) while the axis is at zero velocity (interface signal “axis stop” is active).
   The total drift value is the sum of the basic drift value and the additional drift value.
   Automatic drift compensation for a position-controlled axis is performed under the following conditions:
   - The axis is at zero velocity
   - There is no traverse request for the axis

DRIFT_LIMIT

The additional drift value calculated during the automatic drift compensation process can be limited by MD 36710: DRIFT_LIMIT (drift limit value for automatic drift compensation). If the additional drift value exceeds the value entered in MD: DRIFT_LIMIT, alarm 25070 “Drift value too large” is signaled and the additional drift value is limited to this value. The limit is entered as a percentage of the maximum manipulated variable (100%).
2.8 Drift compensation (for SINUMERIK FM-NC only)

Service display

The effect of the drift compensation can be monitored on the basis of the following error displayed in menu “Service display” in the Diagnosis operating area. If the axis or spindle is at zero velocity, the following error displayed should be zero.

Direct measuring system

The application of direct measuring systems combined with activation of “Automatic drift compensation” (MD 36700: DRIFT_ENABLE=1) causes the relevant axis to oscillate as a result of mechanical reversal errors.

The oscillation amplitude depends on the size of the backlash, the total servo gain and the concrete dynamic conditions (e.g. mass, vertical or horizontal axis).
2.9 Electronic weight compensation

Precondition

This function is available only for use in conjunction with SIMODRIVE 611D.

Note

The “Electronic weight compensation” functionality is not currently available for the combination SINUMERIK 840Di and SIMODRIVE 611 universal drive. The parameters required for the function cannot be transferred to the drive via the PROFIBUS–DP.

Response without-electronic weight compensation

The system responds as follows in the case of weight-bearing axes without programmed weight compensation:

1. Brake holds Z
2. Brake is released, controller enable, pulse enable
3. Axis Z is lowered
4. After some delay, the control holds the axis in position

Fig. 3-30 Lowering of a vertical axis without electronic weight compensation

Lowering of the axis (Z) after release of the brake is not a desirable effect. The greater the reset time set with SIMODRIVE 611D-MD 1409: SPEEDCTRL_INTEGRATOR_TIME_1, the further the axis is lowered. Through activation of the electronic weight compensation function, it is possible to minimize the amount by which the axis is lowered.

Response with electronic weight compensation

The electronic weight compensation function prevents weight-bearing, vertical axes from sagging when the control is switched on. This switch-on process is illustrated in the figure below.
2.9 Electronic weight compensation

1. Brake holds Z
2. Brake is released, controller enable, pulse enable, weight compensation torque
3. Axis Z stays in position

![Diagram of electronic weight compensation](image)

**Fig. 3-31 Lowering of a vertical axis with electronic weight compensation**

**Note**

This function is available only in conjunction with SIMODRIVE 611D.

**Interaction with traverse against fixed stop**

The “Electronic weight compensation” and “Traverse against fixed stop” functions may be used simultaneously, but the following special points should be noted in this respect:

The electronic weight compensation may **not** be used to offset the zero point for the fixed stop torque or fixed stop force as it is unsuitable for this purpose.

- If, for example, the axis requires 30% weight compensation in a case where 40% fixed stop torque is programmed in the same direction, then the actual torque with which the axis presses against the fixed stop only corresponds to 10% of rated torque.

- If 40% fixed stop torque is programmed in the other direction (in the opposite direction to weight compensation, i.e. in direction in which axis would drop) in the same situation described above, then the actual torque with which the axis presses against the fixed stop corresponds to 70% of rated torque.

- If the axis requires, for example, 30% weight compensation, then it is **not** possible to approach a fixed stop if less than 30% stop torque is programmed. This would limit the drive torque to such a degree that the control would not be able to keep the axis in position and it would drop.
These characteristics of the traverse against fixed stop function with vertical axes are determined by the available options for torque limitation in the drive. They are neither improved nor impaired by the weight compensation function.

**Activation**

The function is activated by setting axis-specific MD 32460: TORQUE_OFFSET to a value other than zero and becomes operative after the next RESET or POWER ON or selection of softkey “Set MD active”.

**Deactivation**

The function is deselected by setting axis-specific MD 32460: TORQUE_OFFSET to zero. The deselection takes effect after the next RESET or POWER ON or on selection of softkey “Set MD active”.

SINUMERIK 840D/840Di/810D/FM-NC Extension Functions (FB2) – 04.00 Edition 2/K3/2-91
2.9 Electronic weight compensation

Notes
Supplementary Conditions

3.1 Availability

The individual compensation types are:

- Backlash compensation
- Leadscrew error and measuring system compensation
- Multi-dimensional beam sag compensation
- Manual quadrant error compensation
- Automatic quadrant error compensation (neural network) compensation
- Automatic drift compensation for analog speed setpoints
- Electronic weight compensation

“Backlash compensation” function

This function is available for

- SINUMERIK FM-NC with NCU 570, with SW 1 and higher
- SINUMERIK 840D with NCU 571/572/573, SW 1 and higher

“Leadscrew error and measuring system error compensation” function

This function is available for

- SINUMERIK FM-NC with NCU 570, with SW 1 and higher
- SINUMERIK 840D with NCU 571/572/573, SW 1 and higher

“Multi-dimensional beam sag compensation” function

This function is optional and available on

- SINUMERIK 840D with NCU 571/572/573, SW 2 and higher

The function is contained in the export version 840DE with restricted functionality; it is not contained in the FM-NC, 810DE (SW 3.1 and earlier).

- The function is available for the SINUMERIK 810DE in SW 3.2 and higher.
3.1 Availability

“Quadrant error compensation by operator input” function
This function is available for
- SINUMERIK FM-NC with NCU 570, with SW 1 and higher
- SINUMERIK 840D with NCU 571/572/573 with SW 1 and higher

“Automatic quadrant error compensation” function
This function is an option and available on
- SINUMERIK 840D with NCU 571/572/573, SW 2 and higher

“Temperature compensation” function
This function is an option and available on
- SINUMERIK FM-NC with NCU 570, with SW 1 and higher
- SINUMERIK 840D with NCU 571/572/573, SW 1 and higher

“Automatic drift compensation” function
This function is available for
- SINUMERIK FM-NC with NCU 570, with SW 1 and higher

“Electronic weight compensation” function
This function is available for
- SINUMERIK with NCU 571/572/573, SW 3 and higher, in conjunction with SIMODRIVE 611D.

</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Changes effective after Power On: Protection level: 2 / 4

Data type: DWORD | Applies from SW version: 2.1

**Significance:**

For beam sag compensation, the number of required interpolation points must be defined for every compensation table [i].

with: $[i] = \text{Index of compensation table}$

with ($0 \leq i \leq 2 \times \text{maximum number of axes}$)

i.e. $i = 0$: 1. compensation table

$i = 1$: 2. compensation table etc.

The necessary number can be calculated from the defined parameters as follows (see Section 2.3.3):

$\frac{\text{MM_CEC_MAX_POINTS}[t]}{\text{SAN_CEC_STEP}[t]} = \frac{\text{SAN_CEC_MAX}[t] - \text{SAN_CEC_MIN}[t]}{\text{SAN_CEC_STEP}[t]} + 1$

$\text{SAN_CEC_MIN}[t]$: Initial position (system variable)

$\text{SAN_CEC_MAX}[t]$: End position (system variable)

$\text{SAN_CEC_STEP}[t]$: Distance between interpolation points (system variable)

When selecting the number of interpolation points and the distance between them the resulting size of the compensation table and the resulting required memory capacity in the non-volatile user memory must be noted. 8 bytes are required for every compensation value (interpolation point).

If the value 0 is entered, no memory is reserved for the table; i.e. the table does not exist and the function cannot therefore be activated.

**Special cases, errors, ....... Caution!**

When MD 18342: MM_CEC_MAX_POINTS[t] is changed the non-volatile NC user memory is automatically reallocated on power on. This deletes all the user data in the non-volatile user memory (e.g. drive and MMC machine data, tool offsets, part programs etc.).

<td>The additional torque for the electronic weight compensation is entered in the % block of the static torque (calculated from MD1113 x MD1118). It is immediately effective when the current controller is activated. Vertical axes are thus prevented from sagging when the controller enabling signal is set, particularly when the speed controller reset time setting is high. 100% corresponds to the static torque of the axis drive. With the speed controller deactivated, a positive value would move the drive in a positive traversing direction (see also MD 32100: AX_MOTION_DIR for further details). If, therefore, the positive traversing direction is upwards (axis is raised), then a positive value must be entered for the weight compensation.Conversely, a positive traversing direction downwards would call for a negative value. MD is effective only for SIMODRIVE 611D drive systems.</td>

<td>0</td>
<td>0</td>
<td></td>
<td></td>
<td>NEW_CONF</td>
<td>2</td>
<td></td>
<td>BOOLEAN</td>
<td>--</td>
</tr>
</tbody>
</table>

Significance:

1: Friction compensation with amplitude adaptation is enabled for the axis. With friction compensation quadrant errors on circular contours can be compensated.

Often, the injection amplitude of the friction compensation value is not constant over the entire acceleration range. In this case, for high accelerations a smaller compensation value must be injected than for small accelerations to achieve optimum friction compensation.

The parameters of the adaptation curve (see Fig. 2-14) must be determined and entered in the machine data.

0: Friction compensation with amplitude adaptation must be enabled for the axis.

<td>0</td>
<td>0</td>
<td></td>
<td></td>
<td>NEW_CONF</td>
<td>2</td>
<td>mm/min</td>
<td>DOUBLE</td>
<td>--</td>
</tr>
</tbody>
</table>

Significance:

With machine data MD 32520: FRICT_COMP_CONST_MAX the magnitude of the (maximum) injection amplitude of the friction compensation value is defined. This value is injected over the entire acceleration range for friction compensation without adaptation.

In the case of friction compensation with adaptation, this value is merely applied in the acceleration range B2 of the adaptation characteristic (see Chapter 2, subsection "Conv. friction compensation").

**MD irrelevant for...**

### 32530 MD number  
**FRICT_COMP_CONST_MIN[n]**  
Minimum friction compensation value [setpoint branch]: 0  

<table>
<thead>
<tr>
<th>Default value: 0</th>
<th>Min. input limit: 0</th>
<th>Max. input limit: plus</th>
</tr>
</thead>
<tbody>
<tr>
<td>Changes effective after NEW_CONF</td>
<td>Protection level: 2</td>
<td>Unit: mm/min</td>
</tr>
</tbody>
</table>

Data type: DOUBLE  
Protection level: 2  
Applies from SW version: 1.1  

**Significance:**  
The minimum friction compensation value is needed only if “Friction compensation with adaptation” is active (MD 32510: FRICT_COMP_ADAPT_ENABLE = 1).  
The friction compensation amplitude entered in FRICT_COMP_CONST_MIN is applied in the acceleration range B4 (\(a \geq a_3\)) of the adaptation characteristic (see Section 2, subsection “Conv. friction compensation”).

**MD irrelevant for ....**  
MD 32510: FRICT_COMP_ADAPT_ENABLE = 0  
MD 32490: FRICT_COMP_MODE = 2 (neural QEC)

**Special cases, .....**  
In exceptional cases, the value programmed for FRICT_COMP_CONST_MIN may even be higher than the setting for MD 32520: FRICT_COMP_CONST_MAX.

**Related to ....**

### Description of machine data

<table>
<thead>
<tr>
<th>MD number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>32550</td>
<td>FRICT_COMP_ACCEL1 [n]</td>
</tr>
<tr>
<td>32560</td>
<td>FRICT_COMP_ACCEL2 [n]</td>
</tr>
</tbody>
</table>

#### 32550

- **MD number**: 32550
- **Description**: FRICT_COMP_ACCEL1 [n]
- **Default value**: 0
- **Min. input limit**: 0
- **Max. input limit**: plus
- **Changes effective after**: NEW_CONF
- **Protection level**: 2
- **Unit**: m/s²
- **Data type**: DOUBLE
- **Applies from SW version**: 1.1

**Significance:**

The adaptation acceleration value is only required if "Friction compensation with adaptation" is active.

The adaptation acceleration values 1 to 3 are interpolation points for defining the adaptation curve. The adaptation curve is subdivided into four ranges in which different friction compensation values apply.

Range B1 is defined by FRICT_COMP_ACCEL1 (a1) (see Sect. 2, subsection "Conv. friction compensation").

For the injection amplitude within range B1 the following applies:

\[
\Delta n = \Delta n_{\text{max}} \cdot \frac{a}{a_1} \quad \text{for } a < a_1
\]

MD irrelevant for ...

- MD 32510: FRICT_COMP_ADAPT_ENABLE = 0
- MD 32490: FRICT_COMP_MODE = 2 (neural QEC)

### 32580

**FRICT_COMP_INC_FACTOR**
- **MD number:** 32580
- **Default value:** 1
- **Changes effective after:** Power On
- **Data type:** DOUBLE
- **Significance:** The optimum friction compensation value determined by the circularity test can cause over-compensation of this axis if compensation is activated and axial positioning movements are short.

In such cases, a better setting can be achieved by reducing the amplitude of the friction compensation value (conventional or quadrant error compensation with neural networks) and all positioning movements that are made within an interpolation cycle of the control.

The factor that has to be entered can be determined empirically and can be different from axis to axis because of the different friction conditions. The input range is between 0 to 100% of the value determined by the circularity test.

The default setting is 0; so that no compensation is performed for short traversing movements.

<td>Feedforward control factor for speed feedforward control</td>
<td>1</td>
<td>0</td>
<td>plus</td>
<td>NEW_CONF</td>
<td>DOUBLE</td>
<td>1.1</td>
</tr>
</tbody>
</table>

#### Significance:
In the case of speed feedforward control, a velocity setpoint is also applied directly to the input of the speed controller (see Section 2, subsection "Speed feedforward control"). This additional setpoint can be weighted with a factor (called feedforward control factor).

To ensure that the speed feedforward control is set correctly, the equivalent time constant of the speed control loop must be determined precisely and entered in MD 32810: EQUIV_SPEEDCTRL_TIME.

If the equivalent time constant of the speed control loop is defined exactly, the feedforward control factor has a value of approximately 1. In this case, the system deviation is roughly zero (check by looking at the service display in the operating area Diagnosis).

If the feedforward control factor 0 is entered, feedforward control is deactivated. However, because the calculations are performed anyway, feedforward control must be deactivated with MD: FFW_MODE = 0.

**Application**
In order to achieve excellent machining accuracy at high path velocities, contour inaccuracies due to following error can be eliminated using feedforward control.

**Related to**
- MD 32620: FFW_MODE
- MD 32630: FFW_ACTIVATION_MODE
- MD 32810: EQUIV_SPEEDCTRL_TIME

### 32620 FFW_MODE

<table>
<thead>
<tr>
<th>MD number</th>
<th>Function</th>
<th>Description</th>
<th>Default Value</th>
<th>Min. Input Limit</th>
<th>Max. Input Limit</th>
<th>Access</th>
<th>Data Type</th>
<th>Applies from SW version</th>

</thead>
<tbody>
<tr>
<td>32620</td>
<td>FFW_MODE</td>
<td>Feedforward control mode</td>
<td>1</td>
<td>0</td>
<td>4</td>
<td>RESET</td>
<td>byte</td>
<td>4.3</td>
</tr>
</tbody>
</table>

#### Significance:
FFW_MODE defines the feedforward control mode to be applied on an axis-specific basis.

- 0 = No feedforward control
- 1 = Speed feedforward control with PT1 symmetrization
- 2 = Torque feedforward control (only possible with SINUMERIK 840D) with PT1 symmetrization

Extension of selection by values 3 and 4 in SW 5.3 and later

The default setting is 1 to maintain compatibility to earlier software versions

- 3= Speed feedforward control with Tt symmetrization
- 4= Torque feedforward control (for 840D only) with Tt symmetrization

FFWON and FFWOF are used to activate and deactivate the feedforward control for specific channels on all axes.

To prevent the feedforward control from being affected by these instructions on individual axes, you can define that it is always activated or always deactivated in machine data FFW_ACTIVATION_MODE (see also the section on FFW_ACTIVATION_MODE).

The global option data $ON_FFW_MODE_MASK can conceal torque feedforward control.

If a feedforward control mode is selected (speed or torque feedforward control), it can be programmed additionally in MD 32630: FFW_ACTIVATION_MODE whether the feedforward control can be activated or deactivated by the part program.

Torque feedforward control is an option that must be enabled.

**Application**
In order to achieve excellent machining accuracy at high path velocities, contour inaccuracies due to following error can be eliminated using feedforward control.

**Related to**
- MD 32630: FFW_ACTIVATION_MODE
- MD 32610: VELO_FFW_WEIGHT
- MD 32650: AX_INERTIA
### Description of machine data

**32630**

<table>
<thead>
<tr>
<th>MD number</th>
<th>FFW_ACTIVATION_MODE</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Description</strong></td>
<td>Activate feedforward control from program</td>
</tr>
<tr>
<td>Default value:</td>
<td>1</td>
</tr>
<tr>
<td>Min. input limit:</td>
<td>0</td>
</tr>
<tr>
<td>Max. input limit:</td>
<td>1</td>
</tr>
<tr>
<td>Changes effective after</td>
<td>RESET</td>
</tr>
<tr>
<td>Protection level:</td>
<td>0/0</td>
</tr>
<tr>
<td>Unit:</td>
<td>–</td>
</tr>
<tr>
<td>Data type:</td>
<td>byte</td>
</tr>
<tr>
<td>Applies from SW version:</td>
<td>4.3</td>
</tr>
</tbody>
</table>

**Significance:**

FFW_ACTIVATION_MODE can be set to define whether the feedforward control for this axis/spindle can be switched on and off in the part program.

- **0** = The feedforward control **cannot** be switched on or off by high-level language elements FFWON or FFWOF.
- **1** = Feedforward control can be switched on/off with FFWON or FFWOF.

The default setting is programmed in channel-specific data MD 20150: GCODE_RESET_VALUES. This setting is valid even before the first NC block has been executed.

The last condition to be active remains active even after Reset (and therefore with JOG). Because the feedforward control for all axes of a channel is switched on/off with FFWON or FFWOF, MD:FFW_ACTIVATION_MODE should therefore have identical settings for axes that interpolate with each other.

**Related to:**
- MD 32620: FFW_MODE
- MD 20150: GCODE_RESET_VALUES

</tr>
<tr>
<td>Protection level:</td>
<td>2 / 7</td>
</tr>
<tr>
<td>Unit:</td>
<td>–</td>
</tr>
<tr>
<td>Data type:</td>
<td>Applies from SW version: 4.1</td>
</tr>
</tbody>
</table>

**Significance:**

Activate dynamic stiffness control if bit is set.

With active dynamic stiffness control, higher servo gain factors are possible (MD 32200: POSCTRL_GAIN).

Due to the higher computing load in SIMODRIVE 611D, it may be necessary to adapt the settings of the scanning cycle (current/drive module cycle) in the 611D.

For a single-axis drive module, the default setting (125 µs current, 125 µs speed controller cycle) is sufficient. The speed controller cycle might have to be increased (to 250 µs) for two-axis modules.

**Note:** Currently, according to implementation in the drive, dynamic stiffness control is only possible with the motor measuring system.

**Related to:**

**References**
### Description of machine data

#### 32650 AX_INERTIA

<table>
<thead>
<tr>
<th>MD number</th>
<th>AX_INERTIA</th>
<th>Moment of inertia for torque feedforward control</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default value: 0</td>
<td>Min. input limit: 0</td>
<td>Max. input limit: plus</td>
</tr>
<tr>
<td>Changes effective after NEW_CONF</td>
<td>Protection level: 2</td>
<td>Unit: kgm²</td>
</tr>
<tr>
<td>Data type: DOUBLE</td>
<td>Applies from SW version: 1.1</td>
<td></td>
</tr>
</tbody>
</table>

**Significance:**
In the case of torque feedforward control, an additional current setpoint proportional to the torque is applied directly to the current controller input (see Section 2, subsection “Torque feedforward control”). This value is formed using the acceleration and the moment of inertia. The equivalent time constant of the current control loop must be defined for this purpose and entered in MD 32800: EQUIV_CURRCTRL_TIME.
The total moment of inertia of the axis (drive + load) must also be entered in AX_INERTIA (total moment of inertia referred to motor shaft according to data supplied by machine manufacturer).
When AX_INERTIA and MD 32800: EQUIV_CURRCTRL_TIME are set correctly, the following error is almost zero even during acceleration (check this by looking at the “following error” in the service display).
The torque feedforward control is deactivated if AX_INERTIA is set to 0. However, because the calculations are performed anyway, torque feedforward control must always be deactivated with MD 32620 FFW_MODE = 0 or 1.
Because of the direct current setpoint injection, torque feedforward control is only possible on digital drives (SIMODRIVE 611D).

**MD irrelevant for:**
SINUMERIK FM-NC or MD 32620: FFW_MODE = 0 or 1

**Application:**
Torque feedforward control is required to achieve high contour accuracy where the demands on the dynamics are great.

**Related to:**
MD 32620: FFW_MODE
MD 32630: FFW_ACTIVATION_MODE
MD 32800: EQUIV_CURRCTRL_TIME

#### 32652 AX_MASS

<table>
<thead>
<tr>
<th>MD number</th>
<th>AX_MASS</th>
<th>Axis mass for torque feedforward control</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default value: 0</td>
<td>Min. input limit: 0</td>
<td>Max. input limit: plus</td>
</tr>
<tr>
<td>Changes effective after NEW_CONF</td>
<td>Protection level: 2 / 7</td>
<td>Unit: kg</td>
</tr>
<tr>
<td>Data type: DOUBLE</td>
<td>Applies from SW version: 4.1</td>
<td></td>
</tr>
</tbody>
</table>

**Significance:**
Mass of axis for torque feedforward control.
This MD is used instead of AX_INERTIA on linear drives (DRIVE_TYPE=3).

**Related to:**

**References**

#### 32700 ENC_COMP_ENABLE[n]

<table>
<thead>
<tr>
<th>MD number</th>
<th>ENC_COMP_ENABLE[n]</th>
<th>LEC active [n]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default value: 0</td>
<td>Min. input limit: 0</td>

</tr>
<tr>
<td>Changes effective after NEW_CONF</td>
<td>Protection level: 2 / 7</td>
<td>Unit: –</td>
</tr>
<tr>
<td>Data type: BOOLEAN</td>
<td>Applies from SW version: 1.1</td>
<td></td>
</tr>
</tbody>
</table>

**Significance:**
1: LEC is activated for the axis/measuring system.
With LEC, leadscrew errors and measuring system errors can be compensated.
The function is only enabled if the measuring system has been referenced (IS: “Referenced/synchronized = 1”).
Write protection function (compensation values) active.
0: Interpolatory compensation is not active for the axis/measuring system.

**Index [n] has the following coding:**
encoder no.: 0 or 1

**Related to:**
MD: MM_ENC_COMP_MAX_POINTS Number of interpolation points for interpolatory compensation
IS “Referenced/synchronized 1”
IS “Referenced/synchronized 2”
### 32710 CEC_ENABLE

<table>
<thead>
<tr>
<th>MD number</th>
<th>CEC_ENABLE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default value: 0</td>
<td>Enabling of beam sag compensation</td>
</tr>
<tr>
<td>Min. input limit: 0</td>
<td>Max. input limit: 1</td>
</tr>
<tr>
<td>Changes effective after NEW_CONF</td>
<td>Protection level: 2 / 4</td>
</tr>
<tr>
<td>Data type: BOOLEAN</td>
<td>Applies from SW version: 2.0</td>
</tr>
</tbody>
</table>

**Significance:**

1: “Beam sag compensation” if enabled for the compensation axis. With “beam sag compensation”, inter-axis geometry errors (e.g. beam sag and angularity errors) can be compensated. The function is not enabled in the control until the following conditions have been fulfilled:

- Option “Interpolatory compensation” is set
- Associated compensation tables are available
- Evaluation of the required compensation table is enabled (SD: CEC_TABLE_ENABLE[t] = 1)
- The position measuring system required is referenced (IS “Referenced/synchronized” = 1).
- Write protection function (compensation values) active.

0: “Beam sag compensation” is not enabled for the compensation axis.

**Related to ....**

- MD: MM_CEC_MAX_POINTS[t]  Number of interpolation points for beam sag compensation
- SD: CEC_TABLE_ENABLE[t]  Evaluation of beam sag compensation table t
- IS “Referenced/synchronized 1 or 2”  DB31–48, DBX60.4 or 60.5

### 32711 CEC_SCALING_SYSTEM_METRIC

<table>
<thead>
<tr>
<th>MD number</th>
<th>CEC_SCALING_SYSTEM_METRIC</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default value: 1</td>
<td>Measuring system of beam sag compensation</td>
</tr>
<tr>
<td>Min. input limit: 0</td>
<td>Max. input limit: 1</td>
</tr>
<tr>
<td>Changes effective after RESET</td>
<td>Protection level: 2 / 7</td>
</tr>
<tr>
<td>Data type: BOOLEAN</td>
<td>Applies from SW version: 5</td>
</tr>
</tbody>
</table>

**Significance:**

Compensation data are contained in:

- MD 32711=0: inch system
- MD 32711=1: metric system

The measuring system can be configured for all beam sag compensation tables that affect the same axis. Hereby all position entries are interpolated together with the calculated total axial compensation value in the configured measuring system. External table conversions after the measuring system has been switched over are no longer necessary. Axial configuration of the measuring system is necessary, as only the total axial compensation value is referring unambiguously to a position, not the individual table contents that are calculated in relation to one another.

**Note:** Only effective when MD 10260: CONVERT_SCALING_SYSTEM=1. (see /G2/)

**Related to ....**

- MD 10260: CONVERT_SCALING_SYSTEM  Basic system switchover active
### Description of machine data

<table>
<thead>
<tr>
<th>MD number</th>
<th>Description of machine data</th>
</tr>
</thead>
<tbody>
<tr>
<td>32720</td>
<td>Measuring system of beam sag compensation</td>
</tr>
<tr>
<td>32730</td>
<td>Maximum permissible change value for beam sag compensation</td>
</tr>
</tbody>
</table>

#### MD 32720: CEC_MAX_SUM

- **Default value:** 1
- **Min. input limit:** 0
- **Max. input limit:** 10
- **Changes effective after:** NEW_CONF
- **Protection level:** 2 / 4
- **Unit:**
  - Linear axis: mm
  - Rotary axis: degrees
- **Data type:** DOUBLE
- **Applies from SW version:** 2.1

**Significance:**
In beam sag compensation, the absolute magnitude of the total compensation value (sum of compensation values of all compensation relations) is monitored axially with machine data value CEC_MAX_SUM.

If the determined total compensation value is larger than the maximum value, alarm 20124 is triggered. Program processing is not interrupted. The compensation value output as the additional setpoint is limited to the maximum value.

#### MD 32730: CEC_MAX_VELO

- **Default value:** 10
- **Min. input limit:** 0
- **Max. input limit:** 100
- **Changes effective after:** NEW_CONF
- **Protection level:** 2 / 4
- **Unit:** %
- **Data type:** DOUBLE
- **Applies from SW version:** 2.1

**Significance:**
In beam sag compensation, modification of the total compensation value (sum of the compensation values of all active compensation relations) is limited axially. The maximum change value is defined in this machine data as a percentage of MD 32000: MAX_AX_VELO (maximum axis velocity).

If the change in the total compensation value is greater than the maximum value, alarm 20125 is output. Program processing is however continued. The path not covered because of the limitation is made up as soon as the compensation value is no longer subject to limitation.

### Related to...

- **MD:** CEC_ENABLE
  - Enable beam sag compensation
- **MD:** MAX_AX_VELO
  - Maximum axis velocity
- **SD:** CEC_TABLE_ENABLE[t]
  - Evaluation of beam sag compensation table t
- **IS** "Referenced/synchronized 1 or 2"
  - DB31–48, DBX60.4 or 60.5
### Description of machine data

<table>
<thead>
<tr>
<th>MD number</th>
<th>TEMP_COMP_TYPE</th>
<th>Temperature compensation type</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Default value: 0</td>
<td>Min. input limit: 0</td>
</tr>
<tr>
<td></td>
<td>Changes effective after Power On</td>
<td>Protection level: 2</td>
</tr>
<tr>
<td></td>
<td>Data type: BYTE</td>
<td>Applies from SW version: 1.1</td>
</tr>
</tbody>
</table>

**Significance:**

MD: TEMP_COMP_TYPE, the temperature compensation type effective for the machine axis is activated.

A distinction is made between the following types:

- **0:** No temperature compensation active
- **1:** Position-independent compensation active (compensation value with SD: TEMP_COMP_ABS_VALUE)
- **2:** Position-dependent compensation active (compensation value with SD: TEMP_COMP_SLOPE and SD: TEMP_COMP_REF_POSITION)
- **3:** Position-dependent and position-independent temperature compensation active (compensation values with SD acc. to type 1 and type 2)

Temperature compensation is an option that must be enabled.

**Related to ....**

- SD: TEMP_COMP_ABS_VALUE: Position-dependent temperature compensation value
- SD: TEMP_COMP_REF_POSITION: Reference point for position-dependent temperature compensation
- SD: TEMP_COMP_SLOPE: Gradient for position-dependent temperature compensation
- MD: COMP_ADD_VELO_FACTOR: Velocity violation due to compensation
### 4.1 Description of machine data

**COMP_ADD_VELO_FACTOR**

- **MD number**: 32760
- **Description**: Velocity violation due to compensation
- **Default value**: 0.01
- **Min. input limit**: 0
- **Max. input limit**: 0.1
- **Changes effective after Power On**: Applies from SW version: 1.1
- **Protection level**: 2
- **Unit**: factor
- **Data type**: DOUBLE

**Significance:**

With axial MD: COMP_ADD_VELO_FACTOR the maximum distance that can be traversed because of temperature compensation in one IPO cycle is limited. If the resulting temperature compensation value is above this maximum, it is traversed over several IPO cycles. There is no alarm.

The maximum compensation value per IPO cycle is a factor with reference to the maximum axis velocity (MD: MAX_AX_VELO).

With this machine data the maximum gradient of the temperature compensation \( \tan_{\beta_{\text{max}}} \) is also limited.

**Example of calculation of the maximum gradient \( \tan_{\beta_{\text{max}}} \):**

1. Calculation of the interpolator closed-loop control (see Description of Functions Velocities, Setpoint/Actual-Value Systems, Closed-Loop Control (G2))

   Interpolator closed-loop control = basic system clock rate * factor for interpolation cycle

   \[
   \text{Interpolator closed-loop control} = \text{MD: SYSCLOCK_CYCLE_TIME} \times \text{MD: IPO_SYSCLOCK_TIME_RATIO}
   \]

   Example: MD: SYSCLOCK_CYCLE_TIME = 0.004 [s]
   MD: IPO_SYSCLOCK_TIME_RATIO = 3
   \[
   \Rightarrow \text{Interpolator closed-loop control} = 0.004 \times 3 = 0.012 \text{ [s]}
   \]

2. Calculation of the maximum velocity increase because of a change made to the temperature compensation parameter \( \Delta v_{\text{max}} \)

   \[
   \Delta v_{\text{max}} = \text{MD: MAX_AX_VELO} \times \text{MD: COMP_ADD_VELO_FACTOR}
   \]

   Example: MD: MAX_AX_VELO = 10 000 [mm/min]
   MD: COMP_ADD_VELO_FACTOR = 0.01
   \[
   \Rightarrow \Delta v_{\text{max}} = 10 000 \times 0.01 = 100 \text{ [mm/min]}
   \]

3. Calculation of the traverse distances per interpolator cycle

   \[
   \begin{align*}
   S_1 \ (\text{at } v_{\text{max}}) &= 10 000 \times \frac{0.012}{60} = 2.0 \text{ [mm]} \\
   S_T \ (\text{at } \Delta v_{\text{max}}) &= 100 \times \frac{0.012}{60} = 0.02 \text{ [mm]}
   \end{align*}
   \]

4. Calculation of \( \tan_{\beta_{\text{max}}} \)

   \[
   \tan_{\beta_{\text{max}}} = \frac{S_T}{S_1} = \frac{0.02}{2} = 0.01 \quad \text{(corresponds to value for } \text{COMP_ADD_VELO_FACTOR})
   \]

   \[
   \Rightarrow \beta_{\text{max}} = \arctan 0.01 = 0.57 \text{ degrees}
   \]

   With larger values of SD: TEMP_COMP_SLOPE the maximum gradient (here 0.57 degrees) for the position-dependent temperature compensation value is used internally. There is no alarm.

**Note:** Any additional velocity violation caused by temperature compensation must be taken into account when defining the limit value for velocity monitoring (MD: AX_VELO_LIMIT).

**Related to:**

- MD: TEMP_COMP_TYPE
- SD: TEMP_COMP_ABS_VALUE
- SD: TEMP_COMP_SLOPE
- MD: MAX_AX_VELO
- MD: AX_VELO_LIMIT
- MD: IPO_SYSCLOCK_TIME_RATIO
- MD: SYSCLOCK_CYCLE_TIME

### Description of machine data

#### 36700
**MD number**

<table>
<thead>
<tr>
<th>DRIFT_ENABLE</th>
<th>Automatic drift compensation</th>
</tr>
</thead>
</table>

- **Default value:** 0
- **Min. input limit:** 0
- **Max. input limit:** 1
- **Changes effective after NEW_CONF:**
- **Protection level:** 840D:0; FM-NC:2
- **Unit:** –
- **Data type:** BOOLEAN
- **Applies from SW version:** 1.1

**Significance:**

- MD: DRIFT_ENABLE activates automatic drift compensation.
- 1. Automatic drift compensation is active (only for position-controlled axes/spindles). With automatic drift compensation at zero speed, the control constantly determines the additional drift value required so that the value zero is reached for the following error (compensation criterion).
- The total drift value is therefore composed of the basic drift value (MD: DRIFT_VALUE) and the additional drift value (see Fig. 2-21).
- 0: Automatic drift compensation is not active.
- The drift value is only formed from the basic drift value (MD: DRIFT_VALUE).

**MD irrelevant for:**

- SINUMERIK 840D or for axes/spindles which are not position-controlled

**Related to:**

- MD: DRIFT_LIMIT: Drift limit value for automatic drift compensation
- MD: DRIFT_VALUE: Drift basic value

#### 36710
**MD number**

<table>
<thead>
<tr>
<th>DRIFT_LIMIT</th>
<th>Drift limit value for automatic drift compensation</th>
</tr>
</thead>
</table>

- **Default value:** 0
- **Min. input limit:** 0
- **Max. input limit:** plus
- **Changes effective after NEW_CONF:**
- **Protection level:** 840D:0
- **FM-NC:** 2
- **Unit:** % of manipulated variable (e.g. 10 V / 100%)
- **Data type:** DOUBLE
- **Applies from SW version:** 1.1

**Significance:**

- MD: DRIFT_LIMIT, the magnitude of the additional drift value determined during automatic drift compensation can be limited.
- If the additional drift value exceeds the value entered in MD: DRIFT_LIMIT, alarm 25070 "Drift value too large" is signalled and the additional drift value is limited to this value.

**MD irrelevant for:**

- SINUMERIK 840D or
- MD: DRIFT_ENABLE = 0

**Related to:**

- MD: DRIFT_ENABLE: Automatic drift compensation

#### 36720
**MD number**

<table>
<thead>
<tr>
<th>DRIFT_VALUE</th>
<th>Basic drift value</th>
</tr>
</thead>
</table>

- **Default value:** 0
- **Min. input limit:** 0

- **Changes effective after NEW_CONF:**
- **Protection level:** 840D:0; FM-NC:2
- **Unit:** %
- **Data type:** DOUBLE
- **Applies from SW version:** 1.1

**Significance:**

- The basic drift value entered in MD: DRIFT_VALUE is always injected as an additional speed setpoint.
- The basic drift value is always active (independently of the MD: DRIFT_ENABLE).
- While the automatic drift compensation only applies to position-controlled axes, the basic drift value is also active for speed-controlled axes/spindles.

**MD irrelevant for:**

- SINUMERIK 840D
4.1 Description of machine data

<table>
<thead>
<tr>
<th>38000</th>
<th>MM_ENC_COMP_MAX_POINTS[n]</th>
</tr>
</thead>
<tbody>
<tr>
<td>MD number</td>
<td>Number of interpolation points for LEC (SRAM)</td>
</tr>
</tbody>
</table>

- **Default value:** 0
- **Min. input limit:** 0
- **Max. input limit:** 5000
- **Changes effective after Power On:**
- **Protection level:** 2
- **Unit:** –
- **Data type:** DWORD
- **Applies from SW version:** 1.1

**Significance:**
For leadscrew error compensation, the number of interpolation points required per measuring system must be defined.

The required number can be calculated as follows using the defined parameters (see Section 2.3.2)

$$\text{MD: } \text{MM ENC COMP MAX POINTS} = \frac{\text{AA ENC COMP MAX} - \text{AA ENC COMP MIN}}{\text{AA ENC COMP STEP}} + 1$$

- **$\text{AA ENC COMP MIN}$** Initial position (system variable)
- **$\text{AA ENC COMP MAX}$** End position (system variable)
- **$\text{AA ENC COMP STEP}$** Distance between interpolation points (system variable)

In selecting the number of interpolation points and the distance between them, it is important to take account of the resulting size of the compensation table and the required space in the backed-up NC user memory (SRAM). 8 bytes are required per compensation value (interpolation point).

The index \([n]\) has the following coding: \([\text{encoder no.}]; 0 \text{ or } 1\)

**Caution:**
After any change in MD: MM ENC COMP MAX_POINTS, the backed-up NC user memory is reallocated automatically on power up.

All data in the backed-up NC user memory are then lost (e.g. part programs, tool offsets etc.). Alarm 6020 "Machine data changed – memory reallocated" is signalled.

If reallocation of the NC user memory fails because the total memory capacity available is not sufficient, alarm 6000 "Memory allocation made with standard machine data" is signalled.

In this case the NC user memory is allocated using the default values of the standard machine data.

**References:**
/FB/, S7, "Memory Configuration"
/DA/, "Diagnostic Guide"

**Related to:**
MD: ENC COMP ENABLE[n] Interpolatory compensation active

**References:**
/FB/, S7, "Memory Configuration"
### 4.1 Description of machine data

<table>
<thead>
<tr>
<th>MD number</th>
<th>MM_QEC_MAX_POINTS</th>
</tr>
</thead>
<tbody>
<tr>
<td>MM number</td>
<td>Maximum number of compensation values for QEC with neural networks</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Default value: 0</th>
<th>Min. input limit: 0</th>
<th>Max. input limit: 1024</th>
</tr>
</thead>
<tbody>
<tr>
<td>Changes effective after Power On</td>
<td>Protection level: 2 / 4</td>
<td>Unit: –</td>
</tr>
<tr>
<td>Data type: DWORD</td>
<td>Applies from SW version: 2.1</td>
<td></td>
</tr>
</tbody>
</table>

**Significance:** In quadrant error compensation with neural networks (QEC) the number of required compensation values must be entered for every axis to be compensated.

The required number can be calculated as follows using the defined parameters (see Section 2.6.2):

\[
\text{MA.MM.QEC.MAX.POINTS} \geq (\text{AA.QEC.COARSE.STEPS} + 1) \times \text{AA.QEC.FINE.STEPS}
\]

- \(\text{AA.QEC.COARSE.STEPS}\) Coarse quantization of characteristic (system variable)
- \(\text{AA.QEC.FINE.STEPS}\) Fine quantization of characteristic (system variable)

For “direction-dependent” compensation the number must be greater than or equal to double value of this product.

When selecting coarse or fine quantization, the resulting size of the compensation table and the memory required for it in the non-volatile user memory must be taken into account. 4 bytes are required for every compensation value. If the value 0 is entered, no memory is reserved for the table; i.e. the table does not exist and the function can therefore not be activated.

**Special cases, errors, …**

**Caution!**

If MD: MM_QEC_MAX_POINTS is altered, the non-volatile user memory is automatically re-allocated on system power-on. This deletes all the user data in the non-volatile user memory (e.g. drive and MMC machine data, tool offsets, part programs etc.).

**Note:**

Because the exact number of required interpolation points is not exactly known during the first installation of the function, a large number should be chosen initially. As soon as the characteristics are recorded and saved, the number can be reduced to the required size. After performing a power on again, the saved characteristics can be reloaded.

## 4.2 Description of setting data

### 4.2.1 CEC_TABLE_ENABLE

<table>
<thead>
<tr>
<th>MD number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>41300</td>
<td>Enable evaluation of beam sag compensation table [t]</td>
</tr>
</tbody>
</table>

- **Default value:** 0
- **Min. input limit:** 0
- **Max. input limit:** 1
- **Changes effective immediately:**
- **Protection level:** 7
- **Data type:** BOOLEAN

**Significance:**

1. Evaluation of compensation table [t] is enabled. The compensation table defines, for example, the compensation relation (assignment of basis to compensation axis) with [t] = index of compensation table (see MD: MM_CEC_MAX_POINTS).

   In “beam sag compensation” the compensation axis can be influenced by several tables. SD: CEC_TABLE_ENABLE[t] can be altered by the NC part program or PLC user program to adapt the total compensation value of the machining application (e.g. switch over tables).

   The compensation is not enabled in the control until the following conditions have been fulfilled:
   - Option “Interpolatory compensation” is set
   - Assigned compensation tables exist
   - Beam sag compensation for compensation axis is activated (MD: $MA_CEC__ENABLE= 1)
   - The position measuring system required is referenced (IS “Referenced/synchronized” = 1).

0: Evaluation of the beam sag compensation table [t] is not enabled.

### 4.2.2 CEC_TABLE_WEIGHT

<table>
<thead>
<tr>
<th>MD number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>41310</td>
<td>Weighting factor for beam sag compensation table [t]</td>
</tr>
</tbody>
</table>

- **Default value:** 1.0
- **Min. input limit:** ***
- **Max. input limit:** ***
- **Changes effective immediately:**
- **Protection level:** 7
- **Data type:** DOUBLE

**Significance:**

The compensation value stored in the table [t] is multiplied by the weighting factor. When choosing the weighting factor, ensure that the resulting compensation value does not exceed the maximum value (MD: CEC_MAX_SUM).

With [t] = index of compensation table (see MD: MM_CEC_MAX_POINTS)

If, for example, the weight of the tools on the machine or workpiece to be machined differ greatly and affect the error curve by a change in amplitude, this can be corrected by changing the weighting factor. In beam sag compensation the weighting factor of the table can be altered for specific tools or workpieces by the PLC user program or the NC program by overwriting the setting data. If, however, the progression of the characteristic curve is greatly changed because of differing weights, different compensation tables must be used.

**Related to ...**

- SD: CEC_TABLE_ENABLE[t] Enable evaluation of beam sag compensation table [t]
- MD: $MA_CEC_MAX_SUM Maximum compensation value for beam sag compensation
### 43900 TEMP_COMP_ABS_VALUE

<table>
<thead>
<tr>
<th>SD number</th>
<th>TEMP_COMP_ABS_VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Position-independent temperature compensation value</td>
</tr>
</tbody>
</table>

- **Default value:** 0
- **Min. input limit:** ***
- **Max. input limit:** ***
- **Changes effective immediately:**
- **Protection level:** MMC-MD 9220
- **Unit:** mm or degrees
- **Data type:** DOUBLE
- **Applies from SW version:** 1.1

**Significance:**
With **SD**: TEMP_COMP_ABS_VALUE, the **position-independent** temperature compensation value is defined (see Fig. 2-2). This value depends on the current temperature from the PLC (user program). As soon as position-independent temperature compensation has been activated (MD: TEMP_COMP_TYPE = 1 or 3), this additional compensation value is traversed by the machine axis.

**SD irrelevant for:** MD: TEMP_COMP_TYPE = 0 or 2

**Related to:**
- MD: TEMP_COMP_TYPE - Temperature compensation type
- MD: COMP_ADD_VELO_FACTOR - Velocity violation caused by compensation

---

### 43910 TEMP_COMP_SLOPE

<table>
<thead>
<tr>
<th>SD number</th>
<th>TEMP_COMP_SLOPE</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Gradient for position-dependent temperature compensation</td>
</tr>
</tbody>
</table>

- **Default value:** 0
- **Min. input limit:** ***
- **Max. input limit:** ***
- **Changes effective immediately:**
- **Protection level:** MMC-MD 9220
- **Unit:** mm or degrees
- **Data type:** DOUBLE
- **Applies from SW version:** 1.1

**Significance:**
With **position-dependent** temperature compensation, the error curve of the temperature-dependent actual-value deviation can often be approximated by a straight line. This straight line is defined by a reference point $P_0$ and a gradient $\tan \theta$ (see Fig. 2-2). With **SD**: TEMP_COMP_SLOPE defines the gradient $\tan \theta$. This gradient can be changed by the PLC user program as a function of the current temperature. As soon as position-dependent temperature compensation is active (MD: TEMP_COMP_TYPE = 2 or 3), the axis traverses the compensation value calculated for the current actual position. MD: COMP_ADD_VELO_FACTOR limits the maximum gradient $\tan \theta_{\text{max}}$ of the error curve. This maximum gradient cannot be exceeded.

**SD irrelevant for:** MD: TEMP_COMP_TYPE = 0 or 1

**Special cases, errors:**
When TEMP_COMP_SLOPE is greater than $\tan \theta_{\text{max}}$, gradient $\tan \theta_{\text{max}}$ is used to calculate the position-dependent temperature compensation value internally. No alarm is output.

**Related to:**
- MD: TEMP_COMP_TYPE - Temperature compensation type
- SD: TEMP_COMP_REF_POSITION - Reference position for position-dependent temperature compensation
- MD: COMP_ADD_VELO_FACTOR - Velocity violation caused by compensation
### 4.2 Description of setting data

<table>
<thead>
<tr>
<th>SD number</th>

</thead>
<tbody>
<tr>
<td>Changes effective immediately</td>
<td>Protection level: MMC-MD 9220</td>
<td>Unit: mm or degrees</td>
</tr>
<tr>
<td>Data type: DOUBLE</td>
<td>Applies from SW version: 1.1</td>
<td></td>
</tr>
</tbody>
</table>

**Significance:**

With **position-dependent** temperature compensation, the error curve of the temperature-dependent actual-value deviation can often be approximated by a straight line. This straight line is defined by a reference point $P_0$ and a gradient $\tan \theta$ (see Fig. 2-2). With SD: TEMP_COMP_REF_POSITION the position of the reference point $P_0$ is defined. This reference point position can be changed by the PLC user program as a function of the current temperature. As soon as position-dependent temperature compensation is active (MD: TEMP_COMP_TYPE = 2 or 3), the axis traverses the compensation value calculated for the current actual position.

**SD irrelevant for:**

- MD: TEMP_COMP_TYPE = 0 or 1

**Related to:**

- MD: TEMP_COMP_TYPE
- SD: TEMP_COMP_SLOPE

Brief Description

Mode groups
A mode group consists of a grouping or unit of machine axes, spindles and channels. A mode group can, in principle, be compared to an independent NC control (with several channels). A mode group contains all those channels that always have to operate in the same mode.

Note
In the standard case a mode group exists and is described in

References: /FB/, K1, “Mode Group, Channel, Program Operation Mode”

Channels
Each channel has its own functions for program decoding, block preparation and interpolation. A channel can process a part program independently.

Note
In the standard case a channel exists and is described in

References: /FB/, K1, “Mode Group, Channel, Program Operation Mode”

The processes in several channels of a mode group can be synchronized in the part programs.

Axis/spindle replacement
After control system Power On, an axis/spindle is assigned to a specific channel and can only be utilized in the channel to which it is assigned.

With the function “Axis/spindle replacement” it is possible to enable an axis/spindle and to allocate it to another channel, that means to replace the axis/spindle.

In SW 3 and higher, axis/spindle replacement can be activated both via the part program and via the PLC program.

Detailed Description

2.1 Mode groups

Mode groups

A mode group is an association of NC channels, axes and spindles that are grouped to form a machining unit.

A mode group contains all those channels that always have to operate in the same mode.

Any axis can be programmed in any channel of a certain mode group. A mode group therefore corresponds to an independent, multiple-channel NC.

Example

On large machine tools (machining centers), it may be necessary for a part program to be processed on one part of the machine while new workpieces to be machined need to be clamped and set up on another part. Such tasks usually require two independent NC controls.

With the mode group function, both tasks can be implemented on one NC control with two mode groups because a different mode can be set for each mode group (AUTOMATIC mode for the program processing, JOG for setting up a workpiece).

Mode group assignment

The configuration of a mode group defines the channels, geometry axes, machine axes and spindles which it is to contain.

A mode group consists of one or several channels which must not be assigned to any other mode group. Machine axes, geometry axes and special axes themselves are assigned to these channels. A machine axis can only be assigned to the channels of one mode group and can only traverse in this mode group.

A mode group is configured with the following data:

- Channel-specific MD 10010: ASSIGN_CHAN_TO_MODE_GROUP (channel valid in mode group)
- Configuration data of the channels
2.2 Channels

Note
For more information about the first mode group, please refer to

References: /FB/, K1, “Mode Group, Channel, Program Operation Mode”

2.2.1 Channel synchronization (program coordination)

General

Definition
As an example, double-slide machining operations or real-time processes can only be carried out if it is possible to synchronize processing in two channels. The channels affected shall perform certain processing procedures time-matched. To allow time-matched processing, the relevant channels must be joined to form a synchronization group (mode group).

The channel synchronization is programmed only via the NC language. The affected channels must be assigned to the same mode group.

Coordination
If several channels are involved in the machining of a workpiece, it may be necessary to synchronize program runs in the individual channels. There are special instructions (commands) for this program coordination. In each case, they are listed in one block.
<table>
<thead>
<tr>
<th>Instruction</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>INIT(n,&quot;identifier&quot;,&quot;q&quot;)</td>
<td>Selection of a program for processing in a certain channel. Acknowledgement mode: n (without) or s (synchronous). Name of the program with indication of the path. Name of the channel: Values 1 to 4 possible.</td>
</tr>
<tr>
<td>CLEAR (identifier)</td>
<td>Deletion of a program indicating the program identifier.</td>
</tr>
<tr>
<td>START (n,n,n,)</td>
<td>Start of the programs selected in other channels. Enumeration of the channel numbers: Values 1 to 4 possible.</td>
</tr>
<tr>
<td>WAITM (Mnr, n, n, n, n)</td>
<td>Wait for mark number Mnr for program synchronization in the specified channels n (channel used can be indicated, but this is optional). The mark number must be identical in all channels. Numbers 0 to 9 are possible.</td>
</tr>
<tr>
<td>WAITE (n,n,n)</td>
<td>Waiting for the program end of the channels indicated. (do not indicate program coordination channel).</td>
</tr>
<tr>
<td>SETM(Mnr1, Mnr2, ...Mnri)</td>
<td>Set wait marks Mnr1, Mnr2, ...Mnri for conditional wait with WAITMC() for the channel in which SETM() is issued. The channel thus declares to its partner channels that its wait characteristic is not/no longer fulfilled. The command can be activated in synchronized actions. Up to 10 marks (0 – 9) can be set using one command.</td>
</tr>
<tr>
<td>CLEARM(Mnr1, Mnr2, ...Mnri)</td>
<td>Delete wait marks Mnr1, Mnr2, ...Mnri for conditional wait with WAITMC() for the channel in which CLEARM() is issued. The channel thus declares to its partner channels that its wait characteristic is fulfilled. The command can be activated in synchronized actions. Up to 10 marks (0 – 9) can be deleted using one command.</td>
</tr>
<tr>
<td>WAITMC(Mnr, n1, n2, ...)</td>
<td>Conditional wait in continuous-path mode for the specified wait characteristic Mnr from the specified channels n1, n2, ... nk. The program coordination channel can be indicated, but this is optional. When processing continues after the wait marks from the other channels in the group have arrived, the wait marks of these channels are deleted.</td>
</tr>
</tbody>
</table>
Software version 3

Behavior

When a WAITM() call is reached, the axes in the current channel are decelerated and wait until the mark number specified in the call arrives from the other channels to be synchronized. The group is synchronized when the other channels are also decelerated as they reach their WAITM() command. The synchronized channels then continue operation.

Example of program coordination

Channel 1:

%100
N10 INIT(2,"_N_200_MPF","n")
N11 START(2)
. ; Processing in channel 1
N80 WAITM(1,1,2) ; Waiting for WAIT mark 1 in channel 1 and in channel 2
. ; Further processing in channel 1
N180 WAITM(2,1,2) ; Waiting for WAIT mark 2 in channel 1 and in channel 2
. ; Further processing in channel 1
N200 WAITE(2) ; Waiting for program end of channel 2
N201 M30 ; Program end channel 1, total end
.
.
.

Channel 2:

%200
. ; Processing in channel 2
N70 WAITM(1,1,2) ; Waiting for WAIT mark 1 in channel 1 and in channel 2
. ; Further processing in channel 2
N270 WAITM(2,1,2) ; Waiting for WAIT mark 2 in channel 1 and in channel 2
. ; Further processing in channel 2
N400 M30 ; Program end of channel 2
. ;
Fig. 2-1 Program runs illustrated by example of coordination with WAITM(), unconditional wait

References: /PA/, Programming Guide
Software version 4

Objective

Decelerating and waiting must take place only in cases where not all the channels to be coordinated have set their mark numbers for the purpose of synchronization. Conditional waiting.

The instants in time for generating wait marks and the conditional wait calls are decoupled.

For the purpose of inter-channel communication, marks may even be set when waiting and decelerating are not intended at all. No WAITMC() command. In this case, the channel marks settings remain valid after execution of RESET and NC Start.

Preconditions for conditional wait

To utilize conditional wait with WAITMC() and reduced wait times, the following conditions must be fulfilled:

- Continuous-path mode G64 must be set
- Look Ahead function must be active
- Exact stop (G60, G09) must not be set.
  If exact stop is selected, waiting with WAITMC() corresponds to waiting with WAITM() from SW level 3.

Response

A) Starting with the motion block before the WAITMC() call, the wait marks of the other channels to be synchronized are checked. If these have all been supplied, then the channels continue to operate without deceleration in continuous-path mode. No wait. The path velocity remains unchanged.

B) If at least one wait mark from one of the channels to be synchronized is missing, then the axes start to decelerate from path velocity down to exact stop velocity. A check is now made in every interpolation cycle whether the missing wait marks from the channels to be coordinated have arrived. If they have, then the axes accelerate up to path velocity and continue to operate normally.

C) If the marks to be supplied by the channels to be synchronized have not arrived by the time exact stop velocity is reached, the machining operation is halted until the missing marks appear. When the last required mark appears, the axes are accelerated from standstill up to path velocity.

The following table shows the sequences of events for cases A) – C):
### Deceleration response to conditional wait with WAITMC()

<table>
<thead>
<tr>
<th>With WAITMC</th>
<th>Response</th>
<th>Velocity curve</th>
</tr>
</thead>
<tbody>
<tr>
<td>A) Wait marks of all channels have already arrived</td>
<td>Continued operation with no deceleration</td>
<td><img src="image" alt="Velocity curve A)" /></td>
</tr>
<tr>
<td>B) All wait marks arrived during deceleration from path velocity down to exact stop velocity</td>
<td>Deceleration ceases immediately when last expected wait mark appears. The axes are accelerated back up to path velocity.</td>
<td><img src="image" alt="Velocity curve B)" /></td>
</tr>
<tr>
<td>C) The last wait mark does not arrive until exact stop velocity has been reached.</td>
<td>Brake down to exact stop velocity. When the last required mark appears, the axes are accelerated from exact stop velocity up to path velocity.</td>
<td><img src="image" alt="Velocity curve C)" /></td>
</tr>
</tbody>
</table>

#### Example of conditional wait in continuous-path mode

The example is schematic and shows only those commands that are relevant to the synchronization process.

**Channel 1:**

%100  
N10 INIT(2, ".N_200_MPF","n")  
N11 INIT(3, ".N_300_MPF","n")  
N15 START(2, 3)  
...  
N20 WAITMC(7, 2, 3)  
...  
N40 WAITMC(8, 2)  
...  
N70 M30  

**Channel 2:**

2.3 Axis/spindle replacement

2.3.1 Introduction

General
An axis/spindle is firmly allocated to a certain channel via the machine data. The axis/spindle can be used in this channel only.

Definition
The “Axis/spindle replacement” function allows an axis or spindle to be enabled and assigned to another channel, in other words, to be replaced. Since the spindle function is subordinated to the axis function, only the term “Axis replacement” is used in the following.

Types of axes
According to the channel, we distinguish four types of axes: The reactions at axis change depend on the settings in MD 30552: AUTO_GET_TYPE.

Channel axis
A channel axis can be programmed in the part program and traversed in all modes.

PLC axis
A PLC axis can only be positioned via the PLC.

If a PLC axis is programmed in the part program
in case of MD AUTO_GET_TYPE = 0 an alarm will be output.
in case of MD AUTO_GET_TYPE = 1 an automatic GET will be generated.
in case of MD AUTO_GET_TYPE = 2 an automatic GETD will be generated.

Neutral axis
If a neutral axis is programmed in the part program
in case of MD AUTO_GET_TYPE = 0 an alarm will be output.
in case of MD AUTO_GET_TYPE = 1 an automatic GET will be generated.
in case of MD AUTO_GET_TYPE = 2 an automatic GETD will be generated.

Axis in another channel
This is actually not a proper type of axis. It is the internal state of a replaceable axis. If this happens to be active in another channel (as channel, PLC or neutral axis).

If an axis is programmed in another channel in the part program:
in case of MD AUTO_GET_TYPE = 0 an alarm will be output.
in case of MD AUTO_GET_TYPE = 1 an automatic GET will be generated.
in case of MD AUTO_GET_TYPE = 2 an automatic GETD will be generated.
2.3 Axis/spindle replacement

Note
MD 20110: RESET_MODE_MASK and MD 20112: START_MODE_MASK control the behavior of the axis assignments in RESET, power-up and part program start. The settings for the channels between which axes are to be exchanged must be selected such that there are no incompatibilities in conjunction with MD 30552: AUTO_GET_TYPE (alarms).

References: /FB/, K2, ...

"Actual-Value System for Workpiece"

Display
The current type of axis and the current channel for this axis will be displayed in an axial PLC interface byte. See Section "Axis replacement by PLC".

Preconditions
To allow an axis to be replaced, the following must be defined via channel-specific MD 20070: AXCONF_MACHAX_USED
(machine axis number valid in channel)

and via
axis-specific MD 30550: AXCONF_ASSIGN_MASTER_CHAN
(initial setting of the channel for axis replacement):

1) In which channel can the axis be used and replaced?
2) To which channel shall the axis be allocated with POWER ON?

Example
With 6 axes and 2 channels, the 1st, 2nd, 3rd and 4th axis in channel 1 and the 5th and 6th axis in channel 2 shall be used. It shall be possible to replace the 1st axis, this shall be allocated to channel 2 after POWER ON.

The channel-specific MD must be allocated with:

CHANDATA(1)
AXCONF_MACHAX_USED=(1, 2, 3, 4, 0, 0, 0, 0)

CHANDATA(2)
AXCONF_MACHAX_USED=(5, 6, 1, 0, 0, 0, 0, 0)

The axis-specific MD must be allocated with:

AXCONF_ASSIGN_MASTER_CHAN[AX1]=2

Note
If an axis is not valid in the channel selected, this is displayed by inversion of the axis name on the MMC.
2.3.2 Description

The following diagram shows which axis replacement possibilities are available.

Possible transitions

<table>
<thead>
<tr>
<th>R</th>
<th>RELEASE(AX ...) from NC program</th>
</tr>
</thead>
<tbody>
<tr>
<td>//</td>
<td>RESET key</td>
</tr>
<tr>
<td>R0</td>
<td>Release in neutral state via PLC</td>
</tr>
<tr>
<td>Rn</td>
<td>Release to a spec. channel via PLC</td>
</tr>
<tr>
<td>G</td>
<td>GET (AX ...) from NC program</td>
</tr>
<tr>
<td>GP</td>
<td>GET via PLC</td>
</tr>
<tr>
<td>GD</td>
<td>GET directly from NC program</td>
</tr>
</tbody>
</table>

2.3.3 Axis transfer to neutral state (release)

RELEASE Notation in part program:
RELEASE (axis name, axis name, SPI (spindle no.), ....)
Note
The axis name corresponds to the axis allocations in the system and is either
- AX1, AX2, AX3, ...
or
- the name assigned in MD 10000: AXCONF_MACHAX_NAME_TAB.

With RELEASE (axis name, ...) a dedicated NC block will always be generated.
Exception: The axis is already in the neutral state.
The RELEASE command is interrupted if
- the prerequisites for axis replacement are not fulfilled
  (MD 20070: AXCONF_MACHAX_USED and
  MD 30550: AXCONF.Assign_Master_CHAN)
- the axis is involved in a transformation
- the axis is within an axis network

Note
If the RELEASE command is applied to a gantry master axis, all following axes
are released, too.

<table>
<thead>
<tr>
<th>If ...</th>
<th>and ...</th>
<th>then ...</th>
</tr>
</thead>
<tbody>
<tr>
<td>the axis is released, but not yet transferred with GET ...</td>
<td>... a RESET takes place via the operator panel ...</td>
<td>... the axis is allocated again to the last responsible channel.</td>
</tr>
</tbody>
</table>

2.3.4 Axis takeover

1a) Per command in the part program
GET (axis name, axis name, SPI (spindle no.), ...)
Takeover of an axis is delayed if
- the axis is changing the measuring system
- servo disable is being processed for the axis (transition from control in follow-up/stop and vice versa)
- the axis/spindle disable is set
- the axis has not yet been enabled by the other channel with RELEASE
- interpolation for the axis has not yet been completed (except for a speed-controlled spindle)
With GET (axis name, ...) a separate NC block with search stop is always generated.

Exception: • If the axis is already a channel axis, then no block is generated.

• If the axis is synchronous, (i.e. it has not been swapped to another channel in the meantime or received a signal from the PLC) no extra block is generated either.

1b) GETD command

An axis is fetched directly from another channel with GETD (GET Directly). That means that no suitable RELEASE must be programmed for this GETD in another channel. In addition, another channel communication must be created (e.g. wait marks), since the supplying channel is interrupted with GETD1. If the axis is a PLC axis, replacement is delayed until the PLC has enabled the axis.

Caution:

This programming command interrupts the program run in the channel in which the required axis is currently to be found! (REORG).

Exception: The axis is at the time in a neutral state.

Note

<table>
<thead>
<tr>
<th>If ...</th>
<th>and ...</th>
<th>then ...</th>
</tr>
</thead>
<tbody>
<tr>
<td>the GET command has been programmed, transfer is delayed ...</td>
<td>... a RESET takes place in the channel ...</td>
<td>... the channel does not try any longer to take over the axis.</td>
</tr>
</tbody>
</table>

An axis assumed with GET remains allocated to this channel even after a key RESET or program RESET. The axis can be replaced by programming RELEASE and GET again or will be assigned to the channel defined in MD 30550: AXCONF_ASSIGN_MASTER_CHAN after Power On.

2) Automatically through programming of axis name

Example 1

N1 M3 S1000

N2 RELEASE (SPI(1)) ;=> Transition to neutral state

N3 S3000 ; New speed for released spindle
 ; MD AUTO_GET_TYPE =
 ; 0 => Alarm “Wrong axis type” is output
 ; 1 => GET (SPI(1)) is generated.
 ; 2 => GETD (SPI(1)) is generated.
2.3 Axis/spindle replacement

Example 2

<table>
<thead>
<tr>
<th>Line</th>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N1</td>
<td>RELEASE (AX1)</td>
<td>Transition to neutral state</td>
</tr>
<tr>
<td>N2</td>
<td>G04 F2</td>
<td>Motion of released axis</td>
</tr>
<tr>
<td>N3</td>
<td>G0 X100 Y100:</td>
<td>Positioning the released axis:</td>
</tr>
</tbody>
</table>

MD AUTO_GET_TYPE =

0 => Alarm “Wrong axis type” is output
1 => GET (AX1) is generated.
2 => GETD (AX1) is generated.

Example 3

<table>
<thead>
<tr>
<th>Line</th>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N1</td>
<td>RELEASE (AX1)</td>
<td>Transition to neutral state</td>
</tr>
<tr>
<td>N2</td>
<td>G04 F2</td>
<td>Motion of released axis</td>
</tr>
<tr>
<td>N3</td>
<td>POS (X) = 100:</td>
<td>Positioning the released axis:</td>
</tr>
</tbody>
</table>

MD AUTO_GET_TYPE =

0 => Alarm “Wrong axis type” is output
1 => GET (AX1) is generated.
2 => GETD (AX1) is generated.

*) If the axis is still synchronized, no dedicated block will be generated.

Note

If an automatic GETD is set, the following must be observed:

1. The channels may influence one another.
   (REORG if axis is taken away)

2. With simultaneous access of several channels to an axis it is not known which channel will have the axis at the end.
2.3.5 Examples of an axis replacement

Assumption

With 6 axes and 2 channels, the 1st, 2nd, 3rd and 4th axis in channel 1 and the 5th and 6th axis in channel 2 shall be used. It shall be possible to replace the 2nd axis between the channels and to allocate to channel 1 after POWER ON.

Task

The task is subdivided into the following areas:

- Machine data allocation so that the prerequisites for axis replacement are given.
- Programming of axis replacement between channel 1 and channel 2.

Fulfillment of preconditions

Assignment of channel-specific MD 20070:

AXCONF_MACHAX_USED[1]=(1, 2, 3, 4, 0, 0, 0, 0)
AXCONF_MACHAX_USED[2]=(5, 6, 2, 0, 0, 0, 0, 0)

Assignment of axis-specific MD 30550:

AXCONF_ASSIGN_MASTER_CHAN[AX2]=1

---

Program in channel 1

RELEASE (AX2)
INIT (2, "N_MPF_DIR\N_TAUSH2_MPF", "S")
START (2)
WAITM (1,1,2)
... ; Release of axis AX2
; Selection of program TAUSH2 in channel 2
; Start of program in channel 2
; Waiting for wait mark 1 in channels 1 and 2
... ; Further sequence of operations after axis
... ; M30

Program TAUSH2 in channel 2

... ; Wait for wait mark 1 in channels 1 and 2
WAITM (1,1,2)
GET (AX2)
... ; Assumption of axis AX2
... ; Further sequence of operations after axis
... ; RELEASE (AX2)
... ; M90
2.3.6 Axis replacement via PLC

- The type of an axis can be determined at any time via an interface byte (PLC axis, channel axis, neutral axis)

**TYPE display**

<table>
<thead>
<tr>
<th>NCK =&gt; PLC (DB31– ..., DBB68)</th>

| 1 0 0 0 0 0 0 1 |

**Ex.3:** Neutral axis. Interface processing in K3

| 0 1 0 0 0 0 1 1 |

---

**Fig. 2-3** Changing an axis from K1 to K2 via part program.
• The PLC can request and traverse an axis at any time and in any operating mode.

Specifying TYPE

PLC => NCK (DB31– ..., DBB8)

| 0 | 0 | 0 | 0 | 0 | 0 | 0 |

NC axis is to go in channels 1–10

PLC: Request new type

NC reacts to rising edge

Axis is to become PLC axis

In principle, the PLC must set the signal “Request new type”. It is deleted again after change. This also applies to a channel change with GET and RELEASE.

• The PLC can change an axis from one channel to another.

PLC axes and PLC spindles are traversed via special function modules in the basic PLC program.

FC15: POS_AX positioning of linear and rotary axes
FC16: PART_AX positioning of indexing axes
FC18: SpinCtrl spindle control

Examples

The following diagrams show the IS signal sequences for changing an NC axis to a PLC axis and transferring an NC axis to a neutral axis through the PLC.

<table>
<thead>
<tr>

**Fig. 2-5** Changing an NC axis to a neutral axis through the PLC.
Supplementary Conditions

“Mode group” function

There are up to 10 mode groups for the SINUMERIK 840D and one for the FM-NC.

Number of channels

Up to 10 channels are available on the SINUMERIK 840D and one on the FM-NC.

“Axis/spindle replacement” function

This function is available for

- SINUMERIK 840D with NCU 572/573, with SW 2 and higher

Change to the channel axis

If an axis is changed from PLC axis, neutral axis or axis in another channel to the axis type channel axis, a synchronization must take place.

With this synchronization,
- the current positions are assumed
- the current speed and gear stage is assumed with spindles.

It is therefore obligatory to perform a feed stop which interrupts the active path movement.

If the axis is transferred with GET, this transition is clearly defined by the part program.

If the axis is allocated by the PLC, the program section in which the change takes place is not clearly foreseeable.

(Except by a separate user-specific NC <-> PLC logics)

For this reason, the change to the channel axis is delayed in the following conditions:

- Path mode is active (G64+axes programmed)
- Thread cutting/tapping is active (G33/G331/G332)
3 Supplementary conditions

Change from a channel axis

The change of a channel axis to a neutral axis or PLC axes cannot be performed during an active path operation.

With RELEASE this is caused by the fact that RELEASE must be located in a separate NC block.

If the PLC changes the axis type, a REORG is triggered internally. Therefore, the change with the listed program conditions is delayed.

Block search

During block search with calculation, all GET, GETD or RELEASE blocks are stored and output after the next NC Start.

Exception:

Blocks which are mutually exclusive are deleted.

Example:

N10 RELEASE (AX1)  Blocks are deleted
N40 GET (AX1)        ”
N70 Destination

Change from a channel axis

The change of a channel axis to a neutral axis or PLC axes cannot be performed during an active path operation.

With RELEASE this is caused by the fact that RELEASE must be located in a separate NC block.

If the PLC changes the axis type, a REORG is triggered internally. Therefore, the change with the listed program conditions is delayed.

Block search

During block search with calculation, all GET, GETD or RELEASE blocks are stored and output after the next NC Start.

Exception:

Blocks which are mutually exclusive are deleted.

Example:

N10 RELEASE (AX1)  Blocks are deleted
N40 GET (AX1)        ”
N70 Destination

Brief Description

Overview
The SINUMERIK FM-NC has a local P bus. It is possible to connect modules belonging to the S7-300 system to this local P bus.

FM 354 as 5th axis
The FM-NC can be extended by one axis by connecting the FM 354 module (FM servo).

Implementing NCK I/Os
Apart from the FM 354, you can also connect digital and analog input/output modules to this local P bus. These modules make it possible to provide the FM-NC with digital inputs and outputs.

Detailed Description

2.1 Configuration of local P bus

Overview

The purpose of the local P bus is to extend the functionality of the FM-NC module. An FM 354 (FM servo) and digital input/output modules (SMs) can be connected to this bus. The FM 354 increases the number of FM-NC axes from four to five while the SM modules provide the FM-NC with additional digital inputs and outputs.

Fig. 2-1 shows the local P bus of the FM-NC as an integral component of the overall S7-300 system.
Configuration

The rack configuration determines how many modules can be connected to the local P bus. The maximum possible number the rack can hold is eight (without PLC and IM). The higher the number of modules connected to the P bus of the PLC, the lower the number which may be connected to the local P bus of the FM-NC (see Fig. 2-2).

Example 1: Rack configuration with FM 354 as 5th axis (max. rack configuration per rack tier)

<table>
<thead>
<tr>
<th>Slot no., local P bus:</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
</tr>
</thead>
</table>

Example 2: Rack configuration without FM 354 as 5th axis (max. rack configuration per rack tier)

<table>
<thead>
<tr>
<th>Slot no., local P bus:</th>
<th>1</th>
<th>2</th>
</tr>
</thead>
</table>

Example 3: Rack configuration with FM 354 as 5th axis (rack can be extended by a maximum of three further modules)

<table>
<thead>
<tr>
<th>Slot no., local P bus:</th>
<th>1</th>
<th>2</th>
</tr>
</thead>
</table>

Fig. 2-2 Examples of configuration of S7-300 system rack
### FM 354 as 5th axis

Only one FM 354 module (FM servo) may be connected to the local P bus as the 5th axis.

### Inputs/outputs

It is possible to connect a maximum of 20 digital and analog inputs/outputs (nos. 9 to 28) to the local P bus. Nos. 1 to 8 are always simulation inputs/outputs (see Section 2.3).

**Example:**

- Nos. 1 to 8: No hardware (simulation inputs)
- Nos. 9 to 24: 2 signal modules with 8 digital inputs each
- Nos. 25 to 32: FM 354 with 4 digital hardware inputs (nos. 25 ... 28) and 4 simulation inputs (nos. 29...32)

### Configuration

The configuration of the local P bus is detected by the PLC (CPU) during FM-NC power-up in exactly the same way as that of the P bus.

This rack configuration is displayed in the STEP7 main menu “S7 configuration” (read out SDB2). The “NCU” module must be selected.

In the menu:

**Services**

```
Parameterization
```

**select submenu:**

```
NC CPU Parameterization.
```

The fields “Process alarm generation” and “Local bus segment” must be selected in this menu and activated with OK (SDB100 is generated and transferred to the PLC). The local P bus is then activated.
2.2  FM 354 (FM servo) as 5th axis of the FM-NC

Overview

By connecting an FM 354 (FM servo) to the local P bus of the FM-NC, it is possible to increase the number of machine axes controlled by the FM-NC from four to five. All the parameter settings and calculations for the 5th axis are performed in the FM-NC.

The FM 354 acts as an actual-value input and as a setpoint output for the FM-NC.

Configuration

Please refer to Section 2.1 or SDB100 for “Configuration of 5th axis yes/no”. When the FM 354 (FM servo) is configured correctly as the 5th axis of the FM-NC, the yellow LED “DIAG” flashes according to the set basic clock rate.

Example

If machine data MD10050: SYSCLK_CYCLE_TIME is set to 0.006, then LED “DIAG” flashes in a 6-second cycle (3 s bright and 3 s dark).
Fig. 2-3 shows the FM 354 interfaces to the S7-300 system and the NC machine.

Fig. 2-3 Position of interfaces and front panel elements
2.2 FM 354 (FM servo) as 5th axis of the FM-NC

Interfaces

- **SIMATIC interface**
  Rear panel connectors for connection of FM 354 to further control components via the S7-300 backplane bus (P and K buses)

- **Drive interface**
  9-pin sub D connector (X2) for connecting the drive unit

- **Measuring system interfaces**
  A position encoder can be connected to the 15-pin sub D socket (X3).

- **I/O interface**
  20-pin front panel connector (X1) for connecting the digital inputs/outputs and for wiring power supply
  - PIN 3...6 Digital input 1...4
  - PIN 11...14 Digital output 1...4
  - PIN 19/20 Load power supply 24 V/ground (L+, M)

Displays

- 3 LEDs for error and status displays
- 8 LEDs for digital inputs/outputs
- 1 LED for “Controller message” input (not used for FM-NC)

Machine data

The 5th axis (FM 354) need not be the 5th channel axis of the FM-NC. The 5th axis is parameterized in exactly the same way as the four other axes.

The setpoint output of the FM 354 (on the local P bus) is assigned to an axis by means of MD 30100: $MA_CTRLOUT_SEGMENT_NR[n] = 2$ (local P bus identifier, see Section 6).

The actual-value input (measuring system) is assigned to the appropriate axis via MD 30210: $MA_ENC_SEGMENT_NR[n] = 2$ (local P bus identifier, see Chapter 6).

Important

It is not permissible to mix the axes of the setpoint output and the actual-value input of the 5th axis (FM 354), i.e. the setpoint output and the actual-value input of the 5th axis may only be operated on the same channel axis (see Chapter 9).
2.3 Digital inputs/outputs on local P bus of FM-NC

Overview
Digital input and output modules of the SIMATIC S7-300 system (e.g. SM 321) can be connected to the local P bus of the FM-NC. It is possible to provide the FM-NC with digital inputs and outputs in this way.

For a detailed description of how to handle these inputs/outputs, please refer to References: /FB/, A4, “Digital and Analog NCK I/Os”

The following description contains only a few supplementary notes and references to special features of the local P bus.

Machine data for digital inputs/outputs
In addition to the configuration settings of the digital inputs/outputs in SDB100, the following machine data must also be noted:

- MD10366: $MN_HW_ASSIGN_DIG_FASTIN[0...3]
- MD10368: $MN_HW_ASSIGN_DIG_FASTOUT[0...3]

The following applies to these MDs:

<table>
<thead>
<tr>
<th>MD: 02 0x 01 0x</th>
<th>Byte no.</th>
<th>Submodule no.</th>
<th>Slot on local P bus</th>
<th>Local P bus</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Example: The local P bus of the FM-NC is structured as follows:

<table>
<thead>
<tr>
<th>Slot in local P bus</th>
<th>16 dig. inputs</th>
<th>16 dig. outputs</th>
<th>FM 354 (FM servo)</th>
</tr>
</thead>
<tbody>
<tr>
<td>O9...16</td>
<td>I9...16</td>
<td>I25...28</td>
<td></td>
</tr>
<tr>
<td>O17...24</td>
<td>I17...24</td>
<td>Q25...28</td>
<td></td>
</tr>
</tbody>
</table>

Consequently:

- MD10366: ... IN[0] = 02 02 01 01 I9...16
- MD10366: ... IN[1] = 02 02 02 02 I17...24
- MD10366: ... IN[2] = 02 03 01 01 I25...28
- MD10366: ... IN[3] = 02 00 01 00 Not assigned
- MD10368: ... OUT[0] = 01 01 01 Q9...16
- MD10368: ... OUT[1] = 01 01 02 Q17...24
- MD10368: ... OUT[2] = 03 01 01 Q25...28
- MD10368: ... OUT[3] = 00 01 00 Not assigned

Important
The FM 354 (FM servo) has four digital inputs/outputs which can be addressed via front connector X1. The remaining digital inputs/outputs of the byte (29...32) can be addressed as simulation inputs/outputs.
The following MDs
MD 10350: $MN_FASTIO_DIG_NUM_INPUTS and
MD 10360: $MN_FASTIO_DIG_NUM_OUTPUTS
are used to parameterize the available digital inputs/outputs for the part program (these take into account all inputs/outputs, simulation or hardware).

<table>
<thead>
<tr>
<th>Possible setpoint</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1...8 NCK I/O without hardware (simulation)</td>
</tr>
<tr>
<td>2</td>
<td>9...16 ext. I/O of FM-NC (local P bus)</td>
</tr>
<tr>
<td>3</td>
<td>17...24 ext. I/O of FM-NC (local P bus)</td>
</tr>
<tr>
<td>4</td>
<td>25...32 ext. I/O of FM-NC (local P bus)</td>
</tr>
</tbody>
</table>

Read:
$A_IN[n] \quad n = \text{Number of input}$

Write:
$A_OUT[n] \quad n = \text{Number of output}$

Examples:
- $R1 = A_IN[9]$
  The circuit state of input 9 is stored in $R1$.
- $A_OUT[9] = R1$
  The circuit state (high or low) of $R1$ is output at output 9.
  The state of input 11 is output at output 10.
2.4 Analog inputs/outputs on local P bus of FM-NC

Overview
Analog input/output modules of the SIMATIC S7-300 system (e.g. SM 335) can be connected to the local P bus of the FM-NC in addition to digital modules. For a detailed description of how to handle these input/outputs, please refer to References: /FB/, A4, “Digital and Analog NCK I/O Devices”.

The parameter settings “CPU in Stop, retain last value” is not relevant for use on the local P bus of the FM-NC.

MDs for analog inputs/outputs
Apart from the configuration of the analog inputs/outputs in SDB100, the following machine data must also be noted:
- MD10362: $MN_HW_ASSIGN_ANA_FASTIN
- MD10364: $MN_HW_ASSIGN_ANA_FASTOUT
(See Section 2.3 for meaning of data.)

Setting the available analog inputs/outputs
The following MDs:
- MD10300: $MN_FASTIO_ANA_NUM_INPUTS and
- MD10310: $MN_FASTIO_ANA_NUM_OUTPUTS.
are used for parameterizing the available inputs and outputs that can be used for the part program.

Weighting factor
It is possible to adjust the analog NCK inputs/outputs to the various types of AD/DA converter hardware for reading in the part program by means of the following general machine data:
- MD10320: $MN_FASTIO_ANA_INPUT_WEIGHT
- MD10330: $MN_FASTIO_ANA_OUTPUT_WEIGHT

kann für die analoge NCK E/A eine Anpassung an die hardwaremäßig verschiedenen AD/DA-Wandler für das Lesen im Teileprogramm vorgenommen werden.

The following values can be set for the FM-NC:

INPUT: Measuring range 0...2 V → MD10300 = 2370
       Measuring range 0...10 V → MD10300 = 11851 (default)

OUTPUT: Output range 0...10 V → MD10310 = 11852 (default)
       Output range ± 10 V → MD10310 = 11851

SINUMERIK 840D/840Di/810D/FM-NC Extension Functions (FB2) – 04.00 Edition 2/L1/2-13
Notes
## Supplementary Conditions

### System clock rate for FM-NC with five axes

The basic system clock rate of the FM-NC must be set to 8 ms if the FM-NC has five position-controlled axes, i.e. in contrast to the default setting (0.006), MD10050: $MN_SYSCLOCK_CYCLE_TIME must be set to 0.008.

### Mixing axes of setpoint output with actual value input

The setpoint output and actual value input of an FM 354 (FM servo) acting as a 5th axis must be assigned to the same channel axis.

In other words, if the parameter setting of MD 30100: $MA_CTRLOUT_SEGMENT_NR[0, AX3] is “2”,

then the parameter setting in MD 30210: $MA_ENC_SEGMENT_NR[0, AX3] must also be “2”.

### Number of analog inputs/outputs

The CPU computing time is required on the interpolation plane for processing the digital and analog NCK I/Os connected to the local P bus of the FM-NC. The number of active NCK I/O devices should be restricted to avoid overloading the system. For this reason, only one analog module may be activated on the local P bus for the FM-NC.
Notes
4.1 Machine data for 5th axis

No special signals are required for the 5th axis of the FM-NC (except for those described in References: /FB/, G1, "Gantry Axes").

The following machine data are relevant for parameterization of the 5th axis:

MD 30100: $MA_CTROUT_SEGMENT_NR[n]
MD 30110: $MA_CTROUT_MODULE_NR[n]
MD 30120: $MA_CTROUT_NR[n]
MD 30130: $MA_CTROUT_TYPE[n]  
for setpoint output

MD 30210: $MA_ENC_SEGMENT_NR[n]
MD 30220: $MA_ENC_MODULE_NR[n]
MD 30230: $MA_ENC_INPUT_NR[n]
MD 30240: $MA_ENC_TYPE[n]  
for actual value input

These machine data are described in

References: /FB/, G2; "Velocities, Setpoint/Actual Value Systems, Closed-Loop Control"
4.2  Machine data for digital inputs/outputs of FM-NC

The following machine data are relevant for parameterizing the inputs/outputs:

MD 10350: $MN_FASTIO_DIG_NUM_INPUTS  
MD 10360: $MN_FASTIO_DIG_NUM_OUTPUTS  
MD 10366: $MN_HW_ASSIGN_DIG_FASTIN[0...3]  
MD 10368: $MN_HW_ASSIGN_DIG_FASTOUT[0...3]  

These machine data are described in References: /FB/, A4, “Digital and Analog NCK I/Os”

4.3  Machine data for analog inputs/outputs of FM-NC

The following machine data are relevant for parameterizing the inputs/outputs:

MD10300: $MN_FASTIO_ANA_NUM_INPUTS  
MD10310: $MN_FASTIO_ANA_NUM_OUTPUTS  
MD10320: $MN_FASTIO_ANA_INPUT_WEIGHT  
MD10330: $MN_FASTIO_ANA_OUTPUT_WEIGHT  
MD10362: $MN_HW_ASSIGN_ANA_FASTIN  
MD10364: $MN_HW_ASSIGN_ANA_FASTOUT  

These machine data are described in References: /FB/, A4, “Digital and Analog NCK I/Os”
5.2 Signals for digital and analog inputs/outputs of FM-NC

The signals for the digital inputs and outputs are described in

References: /FB/, A4, “Digital and Analog NCK I/Os”

—
5.2 Signals for digital and analog inputs/outputs of FM-NC

Notes
Example

Parameterizing a 5th axis

The 3rd channel axis (machine axis name Z) must be given the actual value (SSI encoder) via the 5th axis (FM 354) and output the setpoint via the 5th axis (FM 354).

The following machine data must be parameterized for this purpose:

Actual value (SSI encoder):

- MD 30210: $MA_ENC_SEGMENT_NR[0, AX3] = 2$
- MD 30220: $MA_ENC_MODULE_NR[0, AX3] = 1$
- MD 30220: $MA_ENC_INPUT_NR[0, AX3] = 1$
- MD 30220: $MA_ENC_TYPE[0, AX3] = 5$ (SSI encoder)

Setpoint:

- MD 30100: $MA_CTRLOUT_SEGMENT_NR[0, AX3] = 2$
- MD 30110: $MA_CTRLOUT_MODULE_NR[0, AX3] = 1$
- MD 30120: $MA_CTRLOUT_NR[0, AX3] = 1$
- MD 30130: $MA_CTRLOUT_TYPE[0, AX3] = 1$

Data Fields, Lists

Data fields and lists are described in

1.1 TRANSMIT

The functional range offered by TRANSMIT is as follows:

- Face-end machining on turned parts in the turning clamp
  - Holes
  - Contours
- A cartesian coordinate system can be used to program these machining operations.
- The control transforms the programmed traversing movements of the cartesian coordinate system into the traversing movements of the real machine axes (standard application):
  - Rotary axis (1)
  - Infeed axis perpendicular to axis of rotation (2)
  - Longitudinal axis in parallel to axis of rotation (3)
    Linear axes (2) and (3) are perpendicular to one another.
- Tool center offset relative to turning center is permissible.
- The velocity control makes allowance for the limitations defined for rotary motions.
- A path in the cartesian coordinate system must not pass through the turning center point (this restriction applies to SW 2 and 3).

Additional advantages from SW 4

- The tool center point path can pass through the turning center point of the rotary axis.
- The rotary axis does not need to be a modulo axis.
1.2 TRACYL

The functional scope of TRACYL (cylinder generated surface curve transformation) is as follows:

Machining of
- Longitudinal grooves on cylindrical objects,
- Transverse grooves on cylindrical objects,
- Arbitrary groove patterns on cylindrical objects.

The grooving path is programmed in relation to the developed, plane cylinder generated surface.

For machining purposes, the function supports lathes with

- X-C-Z kinematics and
- X-Y-Z-C kinematics.

The control transforms the programmed traversing movements of the cylinder coordinate system into the traversing movements of the real machine axes (standard applications X-C-Z kinematics):
- Rotary axis (1)
- Infeed axis perpendicular to axis of rotation (2)
- Longitudinal axis parallel to axis of rotation (3)

**Note**
Linear axes (2) and (3) are mutually perpendicular. The infeed axis (2) intersects the rotary axis. This constellation does not permit groove side compensation.

Groove side compensation requires X-Y-Z-C kinematics with the following axes:
- Rotary axis (1)
- Infeed axis perpendicular to axis of rotation (2)
- Longitudinal axis parallel to axis of rotation (3)
- Longitudinal axis (4) to supplement (2) and (3) to obtain a right-hand cartesian coordinate system.

**Note**
Linear axes (2), (3) and (4) are perpendicular to one another. This constellation permits groove wall corrections.

- The velocity control makes allowance for the limitations defined for rotary motions.
  TRAANG (Inclined axis)
The “Inclined axis” function is provided for grinding applications. Its functional scope is as follows:

- Machining with inclined infeed axis.
- A cartesian coordinate system can be used for programming purposes.
- The control transforms the programmed traversing movements of the cartesian coordinate system into the traversing movements of the real machine axes (standard application): Inclined infeed axis.
1.3  Chained transformations

Introduction

In SW 5 and higher two transformations can be chained such that the motion parts for the axes from the first transformation are input data for the chained second transformation. The motion parts from the second transformation act on the machine axes.

Chaining possibilities

- In SW 5 the chain may encompass two transformations.
- The second transformation must be “Inclined axis” (TRAANG).
- The first transformation can be:
  - Orientation transformations (TRAORI), incl. universal milling head
  - TRANSMIT
  - TRACYL
  - TRAANG

For details about chained transformations, please refer to Section 2.3, and for further information about other transformations to

References: /FB/, F2, “3 to 5-axis transformations”.

1.4  Activating the transformation MD via part program/softkey (SW 5.2 and later)

SW 5.2 and later

Most existing machine data relevant to kinematic transformations are activated by POWER ON.

In SW 5.2 and later, transformation MD can also be activated via part program/softkey, i.e. the control system need not be booted.

Please refer to Section 2.4 for a detailed description.
Detailed Description

2.1 TRANSMIT

Note
The TRANSMIT transformation described below requires that individual names are assigned to machine axes, channels and geometry axes when the transformation is active.
Compare
MD 10000: AXCONF_MACHAX_NAME_TAB,
MD 20080: AXCONF_CHANAX_NAME_TAB,
MD 20060: AXCONF_GEOAX_NAME_TAB.
Only in this way can unambiguous assignments be made.

Task definition
Complete machining, see diagram.

Legend:
CM  Rotary axis (main spindle)
ASM  Working spindle (milling cutter, drill)
X, Y, Z  Cartesian coordinate system for programming the face-end machining operation (origin in turning center point of face-end)
ZM  Machine axis (linear)
XM  Machine axis (linear)

Fig. 2-1  End face machining of turned part
2.1.1 Preconditions for TRANSMIT

Axis configuration
Before movements can be programmed in the Cartesian coordinate system (acc. to Fig. 2-1 X, Y, Z), the control system must be notified of the relationship between this coordinate system and the real machine axes (CM, XM, ZM, ASM):

- Assignment of names to geometry axes
- Assignment of geometry axes to channel axes
  - General situation (TRANSMIT not active)
  - TRANSMIT active
- Assignment of channel axes to machine axis numbers
- Identification of spindles
- Allocation of machine axis names

With the exception of the “TRANSMIT active” point, the procedure is the same as for the normal axis configuration. If you already know the general steps, you need only read step “Assignment of geometry axes to channel axes” from the list of steps below.

References: /FB/, K2, “Coordinate Systems, Axis Types and Axis Configurations, Actual-Value System for Workpiece, External Zero Offset”

Number of transformations
Up to four (with Software Version 4 and higher: eight) transformation data blocks can be defined for each channel in the system. The machine data names of these transformations start with $MC_TRAFO .. and end with ....n, “n” standing for a number between 1 and 8. The following sections include descriptions of these data:

$MC_TRAFO_TYPE_n
$MC_TRAFO_GEOAX_ASSIGN_TAB_n
$MC_TRAFO_AXES_IN_n.

Number of TRANSMIT structures
Two of the 8 permitted data structures for transformations in the channel may be assigned to the TRANSMIT function. They are characterized by the fact that the value assigned with $MC_TRAFO_TYPE_n is “256”.

For these 2 TRANSMIT transformations, the following machine data must be set in a defined way:

$MC_TRANSMIT_ROT_AX_OFFSET_t
$MC_TRANSMIT_ROT_SIGN_IS_PLUS_t
$MC_TRANSMIT_BASE_TOOL_t
$MC_TRANSMIT_POLE_SIDE_FIX_t (SW 4 and higher)

In this case, “t” specifies the number of the declared TRANSMIT transformation (maximum of 2).
Fig. 2-2  Axis configuration for the example in Fig. 2-1.

The highlighted configuration in Fig. 2-2 applies when a TRANSMIT transformation is active.

Naming the geometry axes

According to the axis configuration overview shown above, the geometry axes to be involved in the TRANSMIT operation must be defined with:

```plaintext
$MC_AXCONF_GEOAX_NAME_TAB[0]="X"
"    _TAB[1]="Y"
"    _TAB[2]="Z"
```

(name selection according to Fig. 2-2, also corresponds to default setting).
### Assignment of geometry axes to channel axes

These assignments are made according to whether or not TRANSMIT is active.

- **TRANSMIT not active**
  - A Y axis is not available.

  ```
  $MC_AXCONF_GEOAX_ASSIGN_TAB[0]=1
  "_TAB[1]=0
  "_TAB[2]=2
  ```

- **TRANSMIT active**
  - The Y axis can be addressed with the part program.

  ```
  $MC_TRAFO_GEOAX_ASSIGN_TAB_1[0]=1
  "_TAB_1[1]=3
  "_TAB_1[2]=2
  ```

The Y axis is the third entry for the channel axes.

### Entry of channel axes

Axes which do not belong to the Cartesian coordinate system are entered.

```
$MC_AXCONF_CHANAX_NAME_TAB[0]="XC"
  "[1]="ZC"
  "[2]="CC"
  "[3]="ASC"
```  

### Assignment of channel axes to machine axes

With the cd of the channel axes as a reference, the machine axis number to which the channel axes have been assigned is transferred to the control system.

```
$MC_AXCONF_MACHAX_USED[0]=2
  "[1]=3
  "[2]=1
  "[3]=4
  "[4]=0
```  

(entries corresponding to Fig. 2-2)

### Identification of spindles

The user defines whether each machine axis is a spindle (value > 0: spindle number) or a path axis (value 0).

```
$MA_SPIND_ASSIGN_TO_MACHAX[0]=1
  "[1]=0
  "[2]=0
  "[3]=2
```  

### Assignment of names to machine axes

With the cd of the machine axes as a reference, a machine axis name is transferred to the control system.

```
$MN_AXCONF_MACHAX_NAME_TAB[0]="CM"
  "[1]="XM"
  "[2]="ZM"
  "[3]="ASM"
```
2.1.2 Settings specific to TRANSMIT

Type of transformation

The following paragraph describes how the transformation type is specified.

TRAFO_TYPE_n

The user must specify the transformation type for the transformation data blocks (maximum n = 8). A value of 256 must be set for TRANSMIT. Example:

$MC_TRAFO_TYPE_1=256

The setting must be made and the values activated with Power On before TRANSMIT or TRANSMIT(t) is called. "t" is the number of the declared TRANSMIT transformation.

Axis image

The following paragraph describes how the transformation axis image is specified.

TRAFO_AXES_IN_n

Three channel axis numbers must be specified for the transformation data block n:

$MC_TRAFO_AXES_IN_1[0]=$ Channel axis number of axis perpendicular to rotary axis
$MC_TRAFO_AXES_IN_1[1]=$ Channel axis number of rotary axis
$MC_TRAFO_AXES_IN_1[2]=$ Channel axis number of axis parallel to Rotary axis

Example for the configuration in Fig. 2-1:
$MC_TRAFO_AXES_IN_1[0]=1
$MC_TRAFO_AXES_IN_1[1]=3
$MC_TRAFO_AXES_IN_1[2]=2

The setting must be made before TRANSMIT or TRANSMIT(t) is called. The axis numbers must refer to the channel axis sequences defined with $MC_TRAFO_GEOAX_ASSIGN_TAB_n.

Rotational position

The rotational position of the Cartesian coordinate system is specified by machine data as described in the following paragraph.

TRANSMIT_ROT_AX_OFFSET_t

The rotational position of the x-y plane of the Cartesian coordinate system in relation to the defined zero position of the rotary axis is specified with:

$MC_TRANSMIT_ROT_AX_OFFSET_t= ... ; degrees

In this case, "t" is substituted by the number of the TRANSMIT transformations declared in the transformation data blocks (t may be maximum 2).
The direction of rotation of the rotary axis is specified by machine data as described in the following paragraph.

If the rotary axis rotates in an anti-clockwise direction on the x-y plane when viewed along the z axis, then the machine axis must be set to "1", but otherwise to "0".

In this case, "t" is substituted by the number of the TRANSMIT transformations declared in the transformation data blocks (t must not be more than 2).

The position of the tool zero point is specified by machine data as described in the following paragraph.

Machine data $MC_TRANSMIT_BASE_TOOL_t$ is used to inform the control of the position of the tool zero point in relation to the origin of the coordinate system declared for TRANSMIT. The machine data has three components for the three axes of the Cartesian coordinate system.

Fig. 2-3 Position of tool zero in relation to origin of the Cartesian coordinate system (see Fig. 2-1).
In this case, \( t \) in front of the index value \([\ ]\) is replaced by the number of the TRANSMIT transformations declared in the transformation data blocks. \((t\) must not be more than 2). 

---

**Replaceable geometry axes**

The PLC is informed when a geometry axis has been replaced using GEOAX( ) through the optional output of an M code that can be set in machine data.

- **MD 22534: TRAFO_CHANGE_M_CODE**

  Number of the M code that is output at the VDI interface in the case of transformation changeover.

---

**Note**

If this machine data is set to one of the values 0 to 6, 17, 30, then no M code is output.

---

**References:** /FB/, K2, "Coordinate Systems, Axis Types and Axis Configurations, Actual-Value System for Workpiece, External Zero Offset"
2.1.3 Activation of TRANSMIT

TRANSMIT

After the settings described above have been made, the TRANSMIT function can be activated:

TRANSMIT or
TRANSMIT(t)

The first declared TRANSMIT function is activated with TRANSMIT. TRANSMIT(t) activates the t-th declared TRANSMIT function. t may not be more than 2.

When TRANSMIT is activated in SW 4 and later, the special processes for pole traversal, etc. according to 2.1.6 become available.

Between activation of the function and deactivation as described below, the traversing movements for the axes of the Cartesian coordinate system can be programmed.

2.1.4 Deactivation of TRANSMIT function

TRAFOOF

Keyword TRAFOOF deactivates an active transformation. When the transformation is deactivated, the base coordinate system is again identical to the machine coordinate system.

An active TRANSMIT transformation is likewise deactivated if one of the other transformations (e.g. TRACYL, TRAANG, TRAORI) is activated in the appropriate channel.

References: /FB/, F2, “3–5-Axis Transformation”.

2.1.5 Special system reactions with TRANSMIT

The transformation can be selected and deselected via part program or MDA.
Please note on selection

- An intermediate motion block is not inserted (phases/radii).
- A spline block sequence must be terminated.
- Tool radius compensation must be deselected.
- The frame which was active prior to TRANSMIT is deselected by the control. (Corresponds to “Reset programmed frame” G500).
- An active working area limitation is deselected by the control for the axes affected by the transformation (corresponds to programmed WALIMOF).
- Continuous path control and rounding are interrupted.
- DRF offsets in transformed axes must have been deleted by the operator.

Please note on deselection

- An intermediate motion block is not inserted (phases/radii).
- A spline block sequence must be terminated.
- Tool radius compensation must be deselected.
- The frame which was active prior to TRANSMIT is deselected by the control. (Corresponds to “Reset programmed frame” G500).
- An activated tool length compensation is incorporated into the transformation by the control.
- Continuous path control and rounding are interrupted.
- DRF offsets in transformed axes must have been deleted by the operator.
- Tool length compensation in the virtual axis (the Y axis in Fig. 2-1) is not implemented.

Restrictions imposed by active TRANSMIT

The restrictions listed below imposed by an activated TRANSMIT function must be noted.

Tool change

Tools may only be changed when the tool radius compensation function is deselected.

Frame

All instructions which refer exclusively to the base coordinate system are permissible (FRAME, tool radius compensation). Unlike the procedure for inactive transformation, however, a frame change with G91 (incremental dimension) is not specially treated. The increment to be traversed is evaluated in the workpiece coordinate system of the new frame – regardless of which frame was effective in the previous block.
Rotary axis

The rotary axis cannot be programmed because it is occupied by a geometry axis and cannot thus be programmed directly as a channel axis.

Pole

SW up to and including 3.x:
Movements through the pole (origin of Cartesian coordinate system) are disabled, i.e. a movement which traverses the pole is stopped in the pole followed by the output of an alarm. In the case of a cutter center offset, the movement is terminated accordingly at the end of the non-approachable area.

SW 4 and higher:
The options for pole traversal and machining operations close to the pole are described in the sections starting at 2.1.6.

Exceptions

Axes affected by the transformation cannot be used
- as a preset axis (alarm)
- to approach the fixed point (alarm)
- for referencing (alarm)

Note

TRANSMIT must be deselected before the tool radius compensation and length compensation are deselected.

Velocity control

Velocity monitoring with TRANSMIT is implemented as standard at the preprocessing stage. Monitoring and limitation in the main run are activated:
- In AUTOMATIC mode if a positioning or oscillation axis has been programmed which is included in the transformation via machine data $MC_TRAFO_AXES_IN_n index 0 or 1.
- On changeover to JOG mode.

The monitoring function is transferred from the main run back to the preprocessing routine if the axes relevant to the transformation process are operated as path axes.

The velocity monitoring function in preprocessing utilizes the machine better than the monitoring in the main run. Furthermore, the main run monitoring function deactivates the Look Ahead.

Interruption of part program

If part program processing is interrupted for JOG, then the following must be noted:
When JOG is selected, the conventional on-line velocity check is activated instead of the optimized velocity check provided in 2.1.6 SW version 4.

If part program processing is interrupted when the transformation is active followed by traversal in JOG mode, then the following must be noted when AUTOMATIC is selected again:

- The transformation is active in the approach block from the current position to the point of interruption. No monitoring for collisions takes place.

**Warning**

The operator is responsible for ensuring that the tool can be re-positioned without any difficulties.

The velocity-optimized velocity planning function (Software Version 4) remains active for as long as the axes relevant to the transformation are traversed in mutual synchronism as path axes. If an axis involved in the transformation is traversed as a positioning axis, the online velocity check remains active until the transformation is deactivated or until all axes involved in the transformation are operating as path axes again. The return to velocity-optimized operation according to 2.1.6 automatically initiates a STOPRE and synchronizes acyclic block preprocessing with the interpolation routine.

If part program processing is aborted with RESET and restarted with START, then the following must be noted:

- The remaining part program is traversed reproducibly only if all axes are traversed to a defined position by means of a linear block (G0 or G1) at the beginning of the part program. A tool which was active on RESET may no longer be taken into account by the control (settable via machine data).

The system response after Power ON is determined by the settings stored in MD 20110: RESET_MODE_MASK and MD 20140: TRAFO_RESET_VALUE.

**References:** /FB/, K2, “Actual-Value System for Workpiece”

Axes cannot be referenced when a transformation is active. Any active transformation is deselected by the control system during a referencing operation.
2.1.6 Machining with TRANSMIT using SW 4.x and higher

**Introduction**

The TRANSMIT transformation has a pole at the zero point of the TRANSMIT plane (example, see Fig.: 2-1, x = 0, Y = 0). The pole is located on the intersection between the radial linear axis and the rotary axis (X and CM). In the vicinity of the pole, small positional changes in the geometry axes generally result in large changes in position in the machine rotary axis. The only exceptions are linear motions into or through the pole.

With SW 4 and higher, a tool center point path through the pole does not cause the part program to be aborted. There are no restrictions with respect to programmable traversing commands or active tool radius compensations. Nevertheless, workpiece machining operations close to the pole are not recommended since these may require sharp feedrate reductions to prevent overloading of the rotary axis.

**New features**

Definition:
A pole is said to exist if the line described by the tool center point intersects the turning center of the rotary axis.

The following cases are examined:
- Under what conditions and by what methods the pole can be traversed
- The response in pole vicinity
- The response with respect to working area limitations
- Monitoring of rotary axis rotations over 360°.

**Pole traversal**

The pole can be traversed by two methods:
- Traversal along linear axis
- Traversal into pole with rotation of rotary axis in pole

**Traversal along linear axis**

![Fig. 2-4 Traversal of x axis through pole](image)

Fig. 2-4 Traversal of x axis through pole
Rotation in pole

![Diagram of pole traversal](image)

Fig. 2-5 Traversal of x axis into pole (a), rotation (b), exit from pole (c)

### Selection of method

The method must be selected according to the capabilities of the machine and the requirements of the part to be machined. The method is selected by machine data:

- **MD 24911**: TRANSMIT_POLE_SIDE_FIX_1
- **MD 24951**: TRANSMIT_POLE_SIDE_FIX_2

The first MD applies to the first TRANSMIT transformation in the channel and the second MD correspondingly to the second TRANSMIT transformation.

<table>
<thead>
<tr>
<th>VALUE</th>
<th>Meaning</th>
</tr>
</thead>
</table>
| 0     | Pole traversal  
The tool center point path (linear axis) must traverse the pole on a continuous path. |
| 1     | Rotation around pole.  
The tool center point path must be restricted to the positive traversing range of the linear axis (in front of turning center). |
| 2     | Rotation around pole.  
The tool center point path must be restricted to the negative traversing range of the linear axis (behind turning center). |

### Special features relating to pole traversal

The method of pole traversal along the linear axis may be applied in the AUTOMATIC and JOG modes.

System response:
Table 2-2  Traversal of pole along the linear axis

<table>
<thead>
<tr>
<th>Operating mode</th>
<th>Status</th>
<th>Reaction</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTOMATIC</td>
<td>All axes involved in the transformation are moved synchronously. TRANSMIT active.</td>
<td>High-speed pole traversal</td>
</tr>
<tr>
<td></td>
<td>Not all axes involved in the transformation are traversed synchronously (e.g. positioning axis). TRANSMIT not active.</td>
<td>Traversal of pole at creep speed</td>
</tr>
<tr>
<td></td>
<td>An applied DRF (external zero offset) does not interfere with the operation. Servo errors may occur close to the pole during application of a DRF.</td>

</tr>
</tbody>
</table>

JOG — Traversal of pole at creep speed

Special features relating to rotation in pole

Precondition: This method is only effective in the AUTOMATIC mode.

MD 24911: TRANSMIT_POLE_SIDE_FIX_1 = 1 or 2
MD 24951: TRANSMIT_POLE_SIDE_FIX_2 = 1 or 2
Value: 1 Linear axis remains within positive traversing range
Value: 2 Linear axis remains within negative traversing range

In the case of a contour that would require the pole to be traversed along the tool center point path, the following three steps are taken to prevent the linear axis from traversing in ranges beyond the turning center:

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Linear axis traverses into pole</td>
</tr>
<tr>
<td>2</td>
<td>Rotary axis turns through 180°, the other axes involved in the transformation remain stationary.</td>
</tr>
<tr>
<td>3</td>
<td>Execution of remaining block. The linear axis now exits from the pole again.</td>
</tr>
</tbody>
</table>

In JOG mode, the motion stops in the pole. In this mode, the axis may exit from the pole only along the path tangent on which it approached the pole. All other motion instructions would require a step change in the rotary axis position or a large machine motion in the cases of minimum motion instructions. They are rejected with alarm 21619.

Traversal close to pole

If a tool center point traverses past the pole, the control system automatically reduces the feedrate and path acceleration rate such that the settings of the machine axes (MD 32000: MAX_AX VELO[AX*] and MD 32300: MAX_AX ACCEL[AX*]) are not exceeded. The closer the path is to the pole, the greater the reduction in the feedrate.
**Tool center point path with corner in pole**

A tool center point path which includes a corner in the pole will not only cause a step change in axis velocities, but also a step change in the rotary axis position. These cannot be reduced by decelerating.

![Diagram of tool center point path with corner in pole](image)

Preconditions:
AUTOMATIC mode, MD 24911: TRANSMIT_POLE_SIDE_FIX_1 = 0 or MD 24951: TRANSMIT_POLE_SIDE_FIX_2 = 0

The control system inserts a traversing block at the step change point. This block generates the **smallest possible rotation** to allow machining of the contour to continue.

**Corner without pole traversal**

![Diagram of corner without pole traversal](image)

Preconditions:
AUTOMATIC mode,
MD 24911: TRANSMIT_POLE_SIDE_FIX_1 = 1 or 2 or MD 24951: TRANSMIT_POLE_SIDE_FIX_2 = 1 or 2
The control system inserts a traversing block at the step change point. This block generates the necessary rotation so that machining of the contour can continue on the same side of the pole.

### Transformation selection in pole

If the machining operation must continue from a position on the tool center path which corresponds to the pole of the activated transformation, then an exit from the pole is specified for the new transformation.

If MD 24911: TRANSMIT_POLE_SIDE_FIX_1= 0 or MD 24951: TRANSMIT_POLE_SIDE_FIX_2= 0 is set (pole traversal), then the smallest possible rotation is generated at the beginning of the block that implements exit from the pole. Depending on this rotation, the axis then traverses either in front of or behind the turning center.

When MD 24911: TRANSMIT_POLE_SIDE_FIX_1= 1 or MD 24951: TRANSMIT_POLE_SIDE_FIX_2= 1 machining continues in front of the turning center (linear axis in positive control range); When MD 24911: TRANSMIT_POLE_SIDE_FIX_1= 2 or MD 24951: TRANSMIT_POLE_SIDE_FIX_2= 2 machining is behind the turning center (linear axis in the negative control range).

### Transformation selection outside pole

The control system moves the axes involved in the transformation without evaluating machine data $MC_TRANSMIT_POLE_SIDE_FIX_t$. In this case, \( t = 1 \) stands for the first and \( t = 2 \) for the second TRANSMIT transformation in the channel.
2.1.7 Working area limitations

When TRANSMIT is active, the pole is replaced by a working area limitation if the tool center point cannot be positioned in the turning center of the rotary axis involved in the transformation. This is the case when the axis perpendicular to the rotary axis (allowing for tool offset) is not positioned on the same radial plane as the rotary axis or if both axes are positioned mutually at an oblique angle. The distance between the two axes defines a cylindrical space in the BCS in which the tool cannot be positioned.

The illegal range cannot be protected by the software limit switch monitoring function since the traversing range of the machine axes is not affected.

![Fig. 2-8 Working area limitation based on offset linear axis](image)

Any motion that leads into the working area limitation is rejected with alarm 21619. Any corresponding part program block is not processed. The control system stops processing at the end of the preceding block.

If the motion cannot be foreseen promptly enough (JOG modes, positioning axes), then the control stops at the edge of the working area limitation.

If a tool center point path leads past the illegal range, the control automatically reduces the feedrate and path acceleration rate to ensure that the settings of the machine axes (MD 32000: MAX_AX_VELO[AX*] and MD 32300: MAX_AX_ACCEL[AX*]) are not exceeded. The closer the path is to the working area limitation, the greater the reduction in the feedrate may be.
2.1.8 Overlaid movements with TRANSMIT in SW 4

The control system cannot predict overlaid motions. However, these do not interfere with the function provided that they are very small (e.g. fine tool offset) in relation to the current distance from the pole (or from working area limitation). With respect to axes that are relevant for the transformation, the transformation monitors the overlaid motion and signals any critical quantity by alarm 21618. This alarm indicates that the block-related velocity planning function no longer adequately corresponds to the actual conditions on the machine. When the alarm is output, the conventional, non-optimized online velocity monitor is therefore activated. The preprocessing routine is re-synchronized with the main run by a REORG generated internally in the control.

Alarm 21618 should be avoided whenever possible since it indicates a state that can lead to axis overload and thus abortion of part program processing.

2.1.9 Monitoring of rotary axis rotations over 360°

Ambiguity of rotary axis positions

The positions of the rotary axis are ambiguous with respect to the number of rotations. The control breaks down blocks containing several rotations around the pole into sub-blocks. This subdivision must be noted with respect to parallel actions (e.g. output of auxiliary functions, block-synchronized positioning axis motions) since the programmed block end is no longer relevant for synchronization, but the end of the first sub-block instead. See:

References: /FB/, H2, "Output of Auxiliary Functions to PLC"
/FB/, S5, "Synchronized Actions"

In single block mode, the control processes individual blocks explicitly. In other modes, the sub-blocks are traversed with Look Ahead like a single block. A limitation of the rotary axis setting range is monitored by the software limit switch monitoring function.

2.1.10 Supplementary Conditions

Look Ahead

All functions requiring Look Ahead (traversal through pole, Look Ahead) work satisfactorily only if the relevant axis motions can be calculated exactly in advance. With TRANSMIT, this applies to the rotary axis and the linear axis perpendicular to it. If one of these axes is the positioning axis, then the Look Ahead function is deactivated by alarm 10912 and the conventional online velocity check activated instead.

Selection of method

The user is responsible for making the optimum choice of "Traversal through pole" or "Rotation around pole". The active prevention of axis traversal through the pole implemented in SW 2 and 3 has been eliminated in SW 4.
### Several pole traversals

A block can traverse the pole any number of times (e.g. programming of a helix with several turns). The part program block is subdivided into a corresponding number of sub-blocks. Analogously, blocks which rotate several times around the pole are likewise divided into sub-blocks. The relevant restrictions applying in SW 2 and 3 have been eliminated in SW 4.

### Rotary axis as modulo axis

The rotary axis can be a modulo rotary axis. However, this is not a mandatory requirement as was the case in SW 2 and 3. The relevant restrictions applying in SW 2 and 3 have been eliminated in SW 4.

### Rotary axis as spindle

If the rotary axis without transformation is used as a spindle, it must be switched to position-controlled mode with SPOS before the transformation is selected.

### REPOS

It is possible to reposition on the sub-blocks produced as a result of the extended TRANSMIT function in SW 4. In this case, the control uses the first sub-block that is closest to the repositioning point in the BCS.

### Block search

In the case of block search with calculation, the block end point (of the last sub-block) is approached in cases where intermediate blocks have been generated as the result of the extended functionality in SW 4.
2.2 TRACYL

Note
The TRACYL transformation described below requires that unique names are assigned to machine axes, channels and geometry axes when the transformation is active. Compare MD 10000: AXCONF_MACHAX_NAME_TAB, MD 20080: AXCONF_CHANAX_NAME_TAB, MD 20060: AXCONF_GEOAX_NAME_TAB. Only in this way can unambiguous assignments be made.

Task definition
Groove machining, see diagram.

Fig. 2-9 Machining grooves on generated cylinder surface with X-C-Z kinematics
The generated cylinder surface curve transformation allows a traversing path to be specified with respect to the generated surface of a cylinder coordinate system. The machine kinematics must correspond to the cylinder coordinate system. It must include one or two linear axes and a rotary axis. The two linear axes must be mutually perpendicular. The rotary axis must be aligned in parallel to one of the linear axes and intersect the second linear axis. In addition, the rotary axis must be co-linear to the cylinder coordinate system.

If there is only one linear axis (X), only grooves which are parallel to the periphery of the cylinder can be generated. In the case of two linear axes (X, Z), the groove pattern on the cylinder is optional. See Fig. 2-9.

If a third linear axis is available (Fig. 2-10) which can produce a right-handed Cartesian coordinate system with the other two linear axes (axis configuration 1), then it is used to offset the tool parallel to the programmed path by means of tool radius compensation, thereby allowing grooves with rectangular traversing section to be generated.

Legend:
XM Infeed axis, perpendicular to rotary axis
YM Supplementary axis
ZM Axis parallel to rotary axis
CM Rotary axis
ASM Working spindle
2.2 TRACYL

**Functionality**

During transformation (both axis configurations), the full functionality of the control is available, both for processing from the NC program and in JOG mode (see 2.2.6).

**Groove cross-section**

In the case of axis configuration 1, longitudinal grooves along the rotary axis are subject to parallel limits only if the groove width corresponds exactly to the tool radius.

Grooves in parallel to the periphery (transverse grooves) are not parallel at the beginning and end.

![Fig. 2-11 Grooves with and without groove wall compensation](image)

2.2.1 Preconditions for TRACYL

**Number of transformations**

Up to 8 transformation data blocks can be defined for each channel in the system. The machine data names of these transformations start with 
$\text{SMC}_\text{TRAFO...}$ and end with 
$\ldots_n$, 
"n" standing for a number between 1 and 8.

The first machine data has the same meaning as described for TRANSMIT:

$\text{SMC}_\text{TRAFO}_\text{GEOAX_ASSIGN_TAB}_n$
$\text{SMC}_\text{TRAFO}_\text{TYPE}_n$
$\text{SMC}_\text{TRAFO}_\text{AXES_IN}_n$.

The special settings described below apply to $\text{SMC}_\text{TRAFO}_\text{TYPE}_n$ and $\text{SMC}_\text{TRAFO}_\text{AXES_IN}_n$ with respect to generated cylinder surface transformation (TRACYL).

**Number of TRACYL structures**

Two of the 8 permitted data structures for transformations may be assigned to the TRACYL function. They are characterized by the fact that the value assigned with $\text{SMC}_\text{TRAFO}_\text{TYPE}_n$ is 512 or 513.

For these TRACYL transformations (maximum of 2), the following machine data must be set in a defined manner:

$\text{SMC}_\text{TRACYL}_\text{ROT_AX_OFFSET}_t$
$\text{SMC}_\text{TRACYL}_\text{ROT_SIGN_IS_PLUS}_t$
$\text{SMC}_\text{TRACYL}_\text{BASE_TOOL}_t$
In this case, \( t \) specifies the number of the declared TRACYL transformation (maximum of 2).

**Axis configuration**

The following overview shows the relationship between the axes of the machine illustrated in Fig. 2-10 and the relevant axis data.

![Axis configuration diagram](image)

**Naming the geometry axes**

According to the above axis configuration overview, the geometry axes to be involved in the TRACYL operation must be defined with:

\[
\text{MD} 35000: \text{SPIND_ASSIGN_TO_MACHAX} \\
\text{MD} 10000: \text{AXCONF_MACHAX_NAME_TAB}
\]

\[
\begin{align*}
1 \text{st machine axis } [\text{AX1}] & : 1 & & \text{CM} \\
2 \text{nd machine axis } [\text{AX2}] & : 0 & & \text{XM} \\
3 \text{rd machine axis } [\text{AX3}] & : 0 & & \text{YM} \\
4 \text{th machine axis } [\text{AX4}] & : 0 & & \text{ZM} \\
5 \text{th machine axis } [\text{AX5}] & : 2 & & \text{ASM} \\
6 \text{th machine axis } [\text{AX6}] & : 0 & & \text{–} \\
7 \text{th machine axis } [\text{AX7}] & : 0 & & \text{–} \\
8 \text{th machine axis } [\text{AX8}] & : 0 & & \text{–}
\end{align*}
\]

\[
\begin{align*}
\text{MC}_\text{AXCONF GEOAX NAME TAB}[0]=&"X" \\
\_TAB[1]=&"Y" \\
\_TAB[2]=&"Z"
\end{align*}
\]

(name selection according to Fig. 2-12, also corresponds to default setting).
Assignment of geometry axes to channel axes

These assignments are made depending on whether or not TRACYL is active.

- **TRACYL not active**
  
  Normal traversal of Y axis.

  ```
  $MC_AXCONF_GEOAX_ASSIGN_TAB[0]=1
  " _TAB[1]=2
  " _TAB[2]=3
  ```

- **TRACYL active**
  
  The Y axis becomes the axis in the direction of the cylinder coordinate system in which the peripheral surface is generated.

  ```
  $MC_TRAFO_GEOAX_ASSIGN_TAB[0]=1
  " _TAB[1]=4
  " _TAB[2]=3
  ```

Entry of channel axes

Axes which do not belong to the Cartesian coordinate system are added.

```
$MC_AXCONF_CHANAX_NAME_TAB[0]="XC"
" _TAB[1]="YC"
" _TAB[2]="ZC"
" _TAB[3]="CC"
" _TAB[4]="ASC"
```

Assignment of channel axes to machine axes

With the cd of the channel axes as a reference, the machine axis number to which the channel axes have been assigned is transferred to the control system.

```
$MC_AXCONF_MACHAX_USED[0]=2
" [1]=3
" [2]=4
" [3]=1
" [4]=5
```

(entries corresponding to Fig. 2-10)

Identification of spindles

The user defines whether each machine axis is a spindle (value > 0: spindle number) or a path axis (value 0).

```
$MA_SPIND_ASSIGN_TO_MACHAX[0]=1
" [1]=0
" [2]=0
" [3]=0
" [4]=2
```

Assignment of names to machine axes

With the cd of the machine axes as a reference, a machine axis name is transferred to the control.

```
$MN_AXCONF_MACHAX_NAME_TAB[0]="CM"
" [1]="XM"
" [2]="YM"
" [3]="ZM"
" [4]="ASM"
```
### 2.2.2 TRACYL-specific settings

<table>
<thead>
<tr>
<th>Type of transformation</th>
<th>The following paragraph describes how the transformation type is specified.</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRAFO_TYPE_n</td>
<td>The user must specify the transformation type for the transformation data blocks (maximum $n = 8$). For TRACYL, a value of 512 must be set for axis configuration 1 and a value of 513 for axis configuration 2. Example:</td>
</tr>
<tr>
<td></td>
<td>MD 24100: TRAFO_TYPE_1 = 512</td>
</tr>
<tr>
<td></td>
<td>The setting must be made and activated with Power ON before TRACYL(d,t) is called. &quot;t&quot; is the number of the declared TRACYL transformation.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Axis image</th>
<th>The following paragraph describes how the transformation axis image is specified.</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRAFO_AXES_IN_n</td>
<td>Three (or 4) channel axis numbers must be specified for the transformation data block $n$:</td>
</tr>
<tr>
<td>$S_{MC_TRAFO_AXES_IN_1[0]}$=</td>
<td>Channel axis number of axis radial to rotary axis</td>
</tr>
<tr>
<td>$S_{MC_TRAFO_AXES_IN_1[1]}$=</td>
<td>Channel axis number of rotary axis</td>
</tr>
<tr>
<td>$S_{MC_TRAFO_AXES_IN_1[2]}$=</td>
<td>Channel axis number of axis parallel to rotary axis</td>
</tr>
<tr>
<td>$S_{MC_TRAFO_AXES_IN_1[3]}$=</td>
<td>Channel axis number of additional axis, parallel to generated cylinder surface of cylinder and perpendicular to rotary axis (if axis configuration 2 is selected)</td>
</tr>
<tr>
<td>Example according to Fig. 2-10:</td>
<td></td>
</tr>
<tr>
<td>$S_{MC_TRAFO_AXES_IN_1[0]}$=1</td>
<td></td>
</tr>
<tr>
<td>$S_{MC_TRAFO_AXES_IN_1[1]}$=4</td>
<td></td>
</tr>
<tr>
<td>$S_{MC_TRAFO_AXES_IN_1[2]}$=3</td>
<td></td>
</tr>
<tr>
<td>$S_{MC_TRAFO_AXES_IN_1[3]}$=2</td>
<td></td>
</tr>
<tr>
<td>The setting must be made and activated with Power ON before TRACYL(d) or TRACYL(d,t) is called. The axis numbers must refer to the channel axis sequences defined with $S_{MC_TRAFO_GEOAX_ASSIGN_TAB_n}$.</td>
<td></td>
</tr>
</tbody>
</table>
The rotational position of the axis on the cylinder peripheral surface perpendicular to the rotary axis must be defined as follows:

![Diagram showing rotational position](image)

**Angle a-b in degrees**

- **a**: Rotational position of rotary axis for \( C = 0 \)
- **b**: Position of \( Y = 0 \)

**Fig. 2-13 Center of rotation of axis on generated cylinder surface**

The rotational position of the peripheral surface in relation to the defined zero position of the rotary axis is specified with:

\[ \text{degrees} \]

In this case, \( t \) is substituted by the number of the TRACYL transformations declared in the transformation data blocks (\( t \) must not be more than 2).

**Direction of rotation**

The direction of rotation of the rotary axis is specified by machine data as described in the following paragraph.

**TRACYL_ROT_SIGN_IS_PLUS_t**

If the direction of rotation of the rotary axis on the x-y plane is counter-clockwise when viewed against the z axis, then the machine data must be set to TRUE, otherwise to FALSE.

\[ \text{TRUE} \]

In this case, \( t \) is substituted by the number of the TRACYL transformations declared in the transformation data blocks (\( t \) must not be more than 2).
Switchable geometry axes

The PLC is informed when a geometry axis has been replaced using GEOAX( ) through the optional output of an M code that can be set in machine data.

- MD 22534: TRAFO_CHANGE_M_CODE

Number of the M code that is output at the VDI interface in the case of transformation changeover.

Note

If this machine data is set to one of the values 0 to 6, 17, 30, then no M code is output.

Position of tool zero

The position of the tool zero point in relation to the origin of the Cartesian coordinate system is specified by machine data as described in the following paragraph.

TRACYL_BASE_TOOL_t

Machine data $MC_TRACYL_BASE_TOOL_t$ is used to inform the control of the position of the tool zero point in relation to the origin of the cylinder coordinate system declared for TRACYL. The machine data has three components for the axes X, Y, Z of the machine coordinate system.

Fig. 2-14 Position of tool zero in relation to machine zero (see Fig. 2-10)
Example:

\[
$MC_TRACYL\_BASE\_TOOL\_t[0]=tx \\
\quad [1]=ty \\
\quad [2]=tz
\]

In this case, "t" is substituted by the number of the TRACYL transformations declared in the transformation data blocks (t must not be more than 2).

2.2.3 Activation of TRACYL

After the settings described above have been made, the TRACYL function can be activated:

- TRACYL(d)
- TRACYL(d,t)

The first declared TRACYL function is activated with TRACYL(d). TRACYL(d,t) activates the t-th declared TRACYL function. t must not be more than 2. The value "d" stands for the current diameter of the cylinder to be machined.

Between activation of the function and deactivation as described below, the traversing movements for the axes of the cylinder coordinate system can be programmed.
2.2.4 Deactivation of TRACYL function

**TRAFOOF**  
Keyword TRAFOOF deactivates an active transformation. When the transformation is deactivated, the base coordinate system is again identical to the machine coordinate system. An active TRACYL transformation is likewise deactivated if one of the other transformations (e.g. TRANSMIT, TRAANG, TRAORI) is activated in the appropriate channel.  
**References:** /FB/, F2, “5-Axis Transformation”

2.2.5 Special system reactions with TRACYL

The transformation can be selected and deselected via part program or MDA.

**Please note on selection**

- An intermediate motion block is not inserted (phases/radii).
- A spline block sequence must be terminated.
- Tool radius compensation must be deselected.
- The frame which was active prior to TRACYL is deselected by the control (corresponds to “Reset programmed frame” G500).
- An active working area limitation is deselected by the control for the axes affected by the transformation (corresponds to programmed WALIMOF).
- Continuous path control and rounding are interrupted.
- DRF offsets must have been deleted by the operator.
- In the case of cylinder generated surface curve transformation with groove wall compensation (axis configuration 2, TRAFO_TYPE_n=513), the axis used for the correction (TRAFO_AXES_IN_n[3]) must be set to zero (y=0) so that the groove is machined in the center of the programmed groove center line.

**Please note on deselection**

The same points apply as for selection.

**Restrictions imposed by active TRACYL**  
The restrictions listed below imposed by an activated TRACYL function must be noted:

- Tool change: Tools may only be changed when the tool radius compensation function is deselected.
Frame
All instructions which refer exclusively to the base coordinate system are permissible (FRAME, tool radius compensation). Unlike the procedure for inactive transformation, however, a frame change with G91 (incremental dimension) is not specially treated. The increment to be traversed is evaluated in the workpiece coordinate system of the new frame—regardless of which frame was effective in the previous block.

Rotary axis
The rotary axis cannot be programmed because it is occupied by a geometry axis and cannot thus be programmed directly as a channel axis.

Axis utilization
The axes
- in the generated cylinder surface perpendicular to the rotary axis (Y) and
- additional axis (YC)
may not be used as a positioning or oscillation axis.

Exceptions
Axes affected by the transformation cannot be used
- as a preset axis (alarm)
- to approach the fixed point (alarm)
- for referencing (alarm)

Note
TRACYL must be deselected before the tool radius compensation and length compensation are deselected.

---

Interuption of part program
The following points must be noted with respect to interrupting part program processing in connection with TRACYL:

AUTOMATIC after JOG
If part program processing is interrupted when a transformation is active and JOG mode selected, then the following must be noted if AUTOMATIC mode is selected again:
- The transformation is active in the approach block from the current position to the point of interruption. No monitoring for collisions takes place.

Warning
The operator is responsible for ensuring that the tool can be re-positioned without any difficulties.
START after
RESET

If part program processing is aborted with RESET and restarted with START, then the following must be noted:

- The remaining part program is traversed reproducibly only if all axes are traversed to a defined position by means of a linear block (G0 or G1) at the beginning of the part program. A tool which was active on RESET may no longer be taken into account by the control (settable via machine data).

2.2.6 JOG

Special features relating to JOG

When generated cylinder surface transformation with groove wall compensation ($MC\_TRAFO\_TYPE = 513) is active in JOG mode, it must be noted that the axes are traversed depending on the preceding status in AUTOMATIC. When groove wall compensation is active, the axes movement therefore differs from the situation when the correction function is deselected. The part program can therefore be continued (REPOS) after a part program interruption.

TRAANG (Inclined axis)

Note

The TRAANG transformation described below requires that unique names are assigned to machine axes, channels and geometry axes when the transformation is active. Compare

MD 10000: AXCONF\_MACHAX\_NAME\_TAB,
MD 20080: AXCONF\_CHANAX\_NAME\_TAB,
MD 20060: AXCONF\_GEOAX\_NAME\_TAB.

Only in this way can unambiguous assignments be made.

Task definition

Grinding operations
Fig. 2-16 Machine with inclined infeed axis

Legend:
X, Z Cartesian coordinate system for programming
C Rotary axis
AS Working spindle
MZ Machine axis (linear)
MU Inclined axis
The following range of machining operations is available:
1. Longitudinal grinding
2. Face grinding
3. Grinding of a specific contour
4. Oblique plunge-cut grinding

![Possible grinding operations](image)

**2.2.7 Preconditions for TRAANG (inclined axis)**

**Axis configuration** To be able to program in the Cartesian coordinate system (see Fig. 2-16: X, Y, Z), it is necessary to inform the control of the correlation between this coordinate system and the actually existing machine axes (MU, MZ):

- Assignment of names to geometry axes
- Assignment of geometry axes to channel axes
  - general situation (inclined axis not active)
  - inclined axis active
- Assignment of channel axes to machine axis numbers
- Identification of spindles
- Allocation of machine axis names
With the exception of the "- Inclined axis active" point, the procedure is the same as for the normal axis configuration.

References: /FB/, K2, "Coordinate Systems, Axis Types and Axis Configurations, Actual-Value System for Workpiece, External Zero Offset"

Number of transformations

Up to 8 transformation data blocks can be defined for each channel in the system. The machine data names of these transformations start with $MC_TRAFO .. and end with .._n, "n" standing for a number between 1 and 8. The following sections include descriptions of these data:

$MC_TRAFO_GEOAX_ASSIGN_TAB_n
$MC_TRAFO_TYPE_n
$MC_TRAFO_AXES_IN_n

Number of inclined axes

Two of the 8 permitted data structures for transformations may be assigned to the inclined axis function. They are characterized by the fact that the value assigned with $MC_TRAFO_TYPE_n is "1024".

Axis configuration

The axes of the grinding machine illustrated in Fig. 2-16 must be entered as follows in the machine data:
The highlighted configuration in Fig. 2-18 applies when TRAANG is active.
2.2.8 TRAANG-specific settings

---

**Type of transformation**

**TRAFO_TYPE_n**

The user must specify the transformation type in machine data 

$MC\_TRAFO\_TYPE\_n$ for the transformation data blocks (maximum n = 8).

The value for an inclined axis is 1024:

MD 24100: TRAFO_TYPE_1=1024

---

**Note**

Changes to the machine data are activated after Power On.

---

**Axis image**

**TRAFO_AXES_IN_n**

Two channel axis numbers must be specified for the transformation data block n:

- $MC\_TRAFO\_AXES\_IN\_1[0]=4$ Channel axis number of inclined axis
- $MC\_TRAFO\_AXES\_IN\_1[1]=1$ Channel axis number of axis parallel to Z
- $MC\_TRAFO\_AXES\_IN\_1[2]=0$ Channel axis number not active

---

**Fig. 2-19 Parameter TRAANG_ANGLE_m**

**Note**

Changes to the machine data are activated after Power On.
Assignment of geometry axes to channel axes

Example:

$\text{MC\_TRAFO\_TYPE\_5} = 8192 \quad \text{Chaining}

$\text{MC\_TRAFO\_AXIS\_IN\_1}[0..x]$

$\text{MC\_TRAFO\_GEOAX\_ASSIGN\_TAB\_5}[0] = 1$  
Definition of geo-axis assignment of transformer 1

$\text{MC\_TRAFO\_GEOAX\_ASSIGN\_TAB\_5}[1] = 6$  
Definition of geo-axis assignment of transformer 1

$\text{MC\_TRAFO\_GEOAX\_ASSIGN\_TAB\_5}[2] = 3$  
Definition of geo-axis assignment of transformer 1

$\text{MC\_TRACON\_CHAIN\_2}[0] = 2$  
Input parameters in TRACON

$\text{MC\_TRACON\_CHAIN\_2}[1] = 3$  
Input parameters in TRACON

$\text{MC\_TRACON\_CHAIN\_2}[2] = 0$  
Input parameters in TRACON

$\text{MC\_TRACON\_CHAIN\_2}[3] = 0$  
Input parameters in TRACON
2.2 TRACYL

---

**Angle of inclined axis**

$\text{TRAANG\_ANGLE}_m$  

Machine data $\text{MC\_TRAANG\_ANGLE\_m}$ is used to inform the control of the angle which exists between a machine axis and the inclined axis in degrees.  

$\text{MC\_TRAANG\_ANGLE\_m} = \text{Angle between a Cartesian axis and the associated inclined machine axis in degrees. The angle is counted positively in the clockwise direction (see Fig. 2-16, angle } \alpha).$  

In this case, $m$ is substituted by the number of the TRAANG transformation declared in the transformation data blocks. $m$ may be maximum 2.

**Permissible angular range**

The permissible angular range is:  

$-90^\circ < \text{TRAANG\_ANGLE}_m < 0^\circ$  

$0^\circ < \text{TRAANG\_ANGLE}_m < 90^\circ$  

No transformation is required for $0^\circ$.  

With $+/- 90^\circ$, the inclined axis is positioned parallel to the second linear axis.

---

**Position of tool zero point**

$\text{TRAANG\_BASE\_TOOL}_m$  

Machine data $\text{MC\_TRAANG\_BASE\_TOOL\_m}$ is used to inform the control of the position of the tool zero point in relation to the origin of the coordinate system declared for the inclined axis function. The machine data has three components for the 3 axes of the Cartesian coordinate system.  

Zero is entered as default.  

The corrections are not converted when the angle is changed.

---

**Optimization of velocity control**

The following machine data are used to optimize the velocity control in jog mode and in positioning and oscillation modes:

$\text{TRAANG\_PARALLEL\_VELO\_RES}_m$  

Machine data $\text{MC\_TRAANG\_PARALLEL\_VELO\_RES\_m}$ is used to set the velocity reserve which is held ready on the parallel axis (see $\text{MC\_TRAFO\_AXES\_IN\_n}[1]$) for the compensatory motion.  

Value range: $0 ... 1$  

0  When value 0 is set, the control automatically determines the reserve: the axes are limited with equal priority (= default setting).
>0 When values of >0 are set, the reserve is fixed at

```
$MC_TRAANG_PARALLEL_VELO_RES_m
```

permissible machine axis velocity value of parallel axis.

The velocity characteristics of the vertical axis are determined by the control on the basis of the reserve.

**TRAANG_PARALLEL_ACCEL_RES_m**

Machine data $MC_TRAANG_PARALLEL_ACCEL_RES_m$ is used to set the axis acceleration reserve which is held ready on the parallel axis (see $MC_TRAFO_AXES_IN_n[1]$) for the compensatory motion.

Value range: 0 ... 1

0 When value 0 is set, the control automatically determines the reserve: the axes are accelerated with equal priority (= default setting).

>0 With values of >0, the acceleration rate is fixed at

```
$MC_TRAANG_PARALLEL_ACCEL_RES_m
```

permissible machine axis velocity value of the parallel axis

The velocity characteristics of the vertical axis are determined by the control on the basis of the reserve.

**Replaceable geometry axes**

The PLC is informed when a geometry axis has been replaced using GEOAX( ) through the optional output of an M code that can be set in machine data.

- MD 22534: TRAFO_CHANGE_M_CODE
  Number of the M code that is output at the VDI interface in the case of transformation changeover.

**Note**

No M code is output if the machine data is set to one of the values 0 to 6, 17 or 30.

**References:** /FB/, K2, “Coordinate Systems, Axis Types, Axis Configurations, Actual-Value System for Workpiece External Zero Offset”
2.2.9 Activation of TRAANG

TRAANG(a)  
After the settings described above have been made, the TRAANG function can be activated:
TRAANG(a)  
or  
TRAANG(a,n)

The first declared "inclined axis" transformation is activated with TRAANG(a). The angle of the inclined axis can be specified with "a". If "a" is omitted or zero entered, the transformation is activated with parameter settings of the previous selection. On the first selection, the presettings according to the machine data apply.
TRAANG(a,n) activates the nth declared "inclined axis" transformation. This form is required only if several transformations are activated in the channel. n must not be more than 2.

Programming variants  
TRAANG(a,1) == TRAANG(a,0) == TRAANG(a,) == TRAANG(a)

Between activation of the function and deactivation as described below, the traversing movements for the axes of the Cartesian coordinate system must be programmed.

2.2.10 Deactivation of TRAANG

TRAFOOF  
Keyword TRAFOOF deactivates an active transformation. When the transformation is deactivated, the base coordinate system is again identical to the machine coordinate system.
An active TRAANG transformation is likewise deactivated if one of the other transformations (e.g. TRACYL, TRANSMIT, TRAORI) is activated in the appropriate channel.

References: /FB/, F2, "5-Axis Transformation"
2.2.11 Special system reactions with TRAANG

The transformation can be selected and deselected via part program or MDA.

Selection and deselection

- An intermediate motion block is not inserted (phases/radii).
- A spline block sequence must be terminated.
- Tool radius compensation must be deselected.
- The current frame is deselected by the control system (corresponds to programmed G500).
- An active working area limitation is deselected by the control for the axes affected by the transformation (corresponds to programmed WALIMOF).
- An activated tool length compensation is included in the transformation by the control.
- Continuous path control and rounding are interrupted.
- DRF offsets must have been deleted by the operator.
- All axes specified in machine data $MC_{TRAFO AXES IN n}$ must be synchronized on a block-related basis (e.g. no traversing instruction with POSA...).

Restrictions

Tool change

Tools may only be changed when the tool radius compensation function is deselected.

Frame

All instructions which refer exclusively to the base coordinate system are permissible (FRAME, tool radius compensation). Unlike the procedure for inactive transformation, however, a frame change with G91 (incremental dimension) is not specially treated. The increment to be traversed is evaluated in the workpiece coordinate system of the new frame – regardless of which frame was effective in the previous block.

Exceptions

Axes affected by the transformation cannot be used
- as a preset axis (alarm)
- to approach the fixed point (alarm)
- for referencing (alarm)
Note
TRAANG must be deselected before the tool radius and length compensations.

Velocity control

The velocity monitoring function for TRAANG is implemented as standard during preprocessing. Monitoring and limitation in the main run are activated:

- In AUTOMATIC mode if a positioning or oscillation axis has been programmed that is involved in the transformation.

- On changeover to JOG mode.

The monitoring function is transferred again from the main run to block preprocessing if the preprocessing is re-synchronized with the main run (currently, for example, on changeover from JOG to AUTOMATIC).

The velocity monitoring function in preprocessing utilizes the dynamic limitations of the machine better than the monitoring function in the main run.

This also applies to machines on which, with oblique machining operations,
2.3 Chained transformations

Introduction

SW 5 and higher supports chaining of the kinematic transformations described here:

- TRANSMIT
- TRACYL
- TRAANG (inclined axis)

as well as those described in

References: /FB/, F2, “3 to 5-axis transformations”

- Orientation transformations
- Universal milling head

with another transformation of the “Inclined axis” type.

Applications

The following is a selection from the range of possible chained transformations:

- Grinding contours that are programmed as a side line of a cylinder (TRACYL) using an inclined grinding wheel e.g. tool grinding.
- Finish cutting of a contour that is not round and was generated with TRANSMIT using inclined grinding wheel.

Note

The transformations described below require that individual names are assigned to machine axes, channels and geometry axes when the transformation is active. Compare MD:

MD 10000: AXCONF_MACHAX_NAME_TAB,
MD 20080: AXCONF_CHANAX_NAME_TAB,
MD 20060: AXCONF_GEOAX_NAME_TAB.

Only in this way can unambiguous assignments be made.
### 2.3 Chained transformations

**Axis configuration**

The following configuration measures are necessary for a chained transformation:

- Assignment of names to geometry axes
- Assignment of names to channel axes
- Assignment of geometry axes to the channel axes
  - General case (no transformation active)
- Assignment of channel axes to machine axis numbers
- Identification of spindle, rotation, modulo for axes
- Allocation of machine axis names
- Transformation-specific settings (for each single transformation and for each chained transformation)
  - Transformation type
  - Axes included in the transformation
  - Assignment of geometry axes to the channel axes with active transformation
  - According to transformation, also rotational position of the coordinate system, direction of rotation, tool zero or original coordinate system angle of inclined axis, etc.

</tbody>
</table>
2.3.1 Activating chained transformations

A chained transformation is activated via:

\[
\text{TRACON}(\text{trf}, \text{par})
\]

with:

- **trf**: Number of the chained transformation:
  - 0 or 1 for first/single chained transformation.
  - If nothing is programmed here, then this has the same meaning as specifying value 0 or 1, i.e. the first/single transformation is activated.
  - 2 for the second chained transformation.
  - (Values not equal to 0 – 2 generate an error alarm).

- **par**: One or more parameters separated by commas for transformations in the chain that require parameters.
  - E.g. angle of inclined axis. If the parameters are not set the default settings or the parameter settings last used are applicable. The use of commas is to ensure that the specified parameters are evaluated in the required sequence, if default settings are to be valid for preceding parameters. In particular, a comma is required before at least one parameter, even though it is not necessary to specify trf. For example:

\[
\text{TRACON}(\ , \ 3.7).
\]

If another transformation was previously activated, it is implicitly disabled by means of TRACON().

2.3.2 Switching off chained transformations

A chained transformation is switched off with TRAFOOF just like any other transformation.

2.3.3 Special characteristics of chained transformations

**Tool data**: A tool is always assigned to the first transformation in a chain. The subsequent transformation then behaves as if the active tool length were zero. Only the basic tool lengths set in the machine data (\_BASE\_TOOL\_) are valid for the first transformation in the chain.

**Example**: Section 6.3 contains configuration examples for single transformations and the transformation chains created from them.
2.4 Activating the transformation MD via part program/softkey (SW 5.2 and later)

2.4.1 Functionality

**SW 5.1 and earlier**
Up to eight different transformations can be set in the control in SW version 5.1 and earlier. The transformation type is set in machine data $MC_TRAFO_TYPE_1$ to $MC_TRAFO_TYPE_8$.

For each transformation group (TRANSMIT, see Section 2.1), TRACYL (see Section 2.2), TRAANG (see Section 2.2.7) and chained transformations (see Section 2.3) there are two transformation data sets, i.e. no more than two transformations can be set from one group, even when the eight available transformations have not yet all been programmed.

**Note**
However, the number of transformation machine data sets is limited as in previous versions.

**Properties**
The machine data listed in Section 4.3 were activated by POWER ON in SW 5.1 and earlier. They are NEWCONFIG-capable in SW 5.2 and higher.

The protection level is now 7 / 7 (KEYSWITCH_0) which means that data can be modified from the NC program without any particular authorization.

Provided that no transformation is selected (activated) when a NEWCONFIG command is issued (regardless whether via the NEWCONF NC program command, the MMC or implicitly following Reset or end of program), the machine data listed above can be altered without restriction and then activated.

Of particular relevance is that new transformations can be configured or existing transformations replaced by one of a different type or deleted, since the modification options are not restricted to re-parameterization of existing transformations.
2.4.2 Supplementary Conditions

Modifying machine data  The machine data which affect an active transformation may not be altered; any attempt to do so will generate an alarm.

This generally applies to all machine data assigned to a transformation via the associated transformation data group. Machine data included in the group of an active transformation, but not currently in use, can be altered (although this would hardly be a meaningful thing to do). For example, it would be possible to change machine data $MC\_TRAFO5\_NUTATOR\_AX\_ANGLE\_N$ for an active transformation with $MC\_TRAFO\_TYPE = 16$ (5-axis transformation with rotatable tool and two mutually perpendicular rotary axes A and B) since this particular machine data is not involved in the transformation.

Please note that machine data $MC\_X\_AXIS\_IN\_OLD\_X\_Z\_PLANE$ may not be altered for an active orientation transformation.

Note

In the case of a program interruption (Repos, deletion of distance to go, ASUBs, etc.), the control system requires a number of different blocks that have already been executed for the repositioning operation. The rule forbidding the machine data of an active transformation to be altered also refers to these blocks.

Example:

Two orientation transformations are set via machine data, e.g. $SMC\_TRAFO\_TYPE\_1 = 16$, $SMC\_TRAFO\_TYPE\_2 = 18$.

Let us assume that the second transformation is active when the NEWCONFIG command is executed. In this instance, only machine data which affect the first transformation may be altered, e.g. $SMC\_TRAFO5\_PART\_OFFSET\_1$, but not, for example, $SMC\_TRAFO5\_BASE\_TOOL\_2$ or $SMC\_X\_AXIS\_IN\_OLD\_X\_Z\_PLANE$.

You could also set, for example, another transformation (TRANSMIT) with $SMC\_TRAFO\_TYPE\_3 = 256$ and parameterize it with other machine data.

Defining geometry axes  Geometry axes must be defined in MD TRAFO\_GEOAX\_ASSIGN\_TAB\_X[n] or MD AXCONF\_GEOAX\_ASSIGN\_TAB[n] before the control system powers up.

Changing the assignment  The assignment between a transformation data set and a transformation is determined by the sequence of entries in $SMC\_TRAFO\_TYPE\_X$. The first transformation data set is assigned to the first entry in the table, the second data set to the second entry, etc. This assignment may (and can) not be altered for an active transformation.

Example:

Three transformations are set, two orientation transformations and one Transmit transformation, e.g.

$SMC\_TRAFO\_TYPE\_1 = 16$ ; Orientation transformation, 1st orientation transformer data set
$SMC\_TRAFO\_TYPE\_2 = 256$ ; Transmit transformation
$SMC\_TRAFO\_TYPE\_3 = 18$ ; Orientation transformation, 2nd orientation transformer data set
The first data set for orientation transformations is assigned to the first transformation (equalling the first orientation transformation and the second transformation data set to the third transformation (equalling the second orientation transformation).

If the third transformation is active when the NEWCONFIG command is executed, it is not permissible to change the first transformation into a transformation of another group (e.g. TRACYL) since, in this case, the third transformation would then not become the second orientation transformation, but the first.

In the above example, however, it is permissible to set another orientation transformation for the first transformation (e.g. using $MC_TRAFO_TYPE_1 = 32) or a transformation from another group as the first transformation (e.g. using $MC_TRAFO_TYPE_1 = 1024, TRAANG), if the second transformation is changed into an orientation transformation at the same time, e.g. with $MC_TRAFO_TYPE_2 = 48.

### 2.4.3 Control response to Power On, mode change, Reset, block search, REPOS

Machine data $MC_RESET_MODE_MASK, $MC_START_MODE_MASK and $MC_TRAFO_RESET_VALUE can be programmed to select a transformation automatically in response to RESET (i.e. including end of program) and / or program start.

This may result in the generation of an alarm, for example, at the end or start of a program, if the machine data of an active transformation has been altered.

To avoid this problem when re-configuring transformations via an NC program, we therefore recommend that NC programs are structured as follows:

```
N 10 TRAFOOF() ; Deselect any active transformation
N20 $MC_TRAFO5_BASE_TOOL_1[0]=0 ; Write machine data
N30 $MC_TRAFO5_BASE_TOOL_1[0]=3 ;
N40 $MC_TRAFO5_BASE_TOOL_1[0]=200;
.
.
N130 NEWCONF ; Accept newly modified machine data
N140 M30
```
2.4.4 List of machine data affected

The machine data which can be made NEWCONFIG-capable are listed below.

All transformations

Machine data which are relevant for all transformations:

- \$MC\_TRAFO\_TYPE\_1 to \$MC\_TRAFO\_TYPE\_8
- \$MC\_TRAFO\_AXES\_IN\_1 to \$MC\_TRAFO\_AXES\_IN\_8
- \$MC\_TRAFO\_GEOAX\_ASSIGN\_TAB\_1 to \$MC\_TRAFO\_GEOAX\_ASSIGN\_TAB\_8

Orientation transformations

Machine data which are relevant for orientation transformations:

- \$MC\_TRAFO5\_BASE\_TOOL\_1 and \$MC\_TRAFO5\_BASE\_TOOL\_2
- \$MC\_TRAFO5\_JOINT\_OFFSET\_1 and \$MC\_TRAFO5\_JOINT\_OFFSET\_2
- \$MC\_TRAFO5\_PART\_OFFSET\_1 and \$MC\_TRAFO5\_PART\_OFFSET\_2
- \$MC\_TRAFO5\_ROT\_AX\_OFFSET\_1 and \$MC\_TRAFO5\_ROT\_AX\_OFFSET\_2
- \$MC\_TRAFO5\_ROT\_SIGN\_IS\_PLUS\_1 and \$MC\_TRAFO5\_ROT\_SIGN\_IS\_PLUS\_2
- \$MC\_TRAFO5\_NON\_POLE\_LIMIT\_1 and \$MC\_TRAFO5\_NON\_POLE\_LIMIT\_2
- \$MC\_TRAFO5\_POLE\_LIMIT\_1 and \$MC\_TRAFO5\_POLE\_LIMIT\_2
- \$MC\_TRAFO5\_AXIS1\_1 and \$MC\_TRAFO5\_AXIS1\_2
- \$MC\_TRAFO5\_AXIS2\_1 and \$MC\_TRAFO5\_AXIS2\_2
- \$MC\_TRAFO5\_BASE\_ORIENT\_1 and \$MC\_TRAFO5\_BASE\_ORIENT\_2
- \$MC\_TRAFO5\_TOOL\_ROT\_AX\_OFFSET\_1 and \$MC\_TRAFO5\_TOOL\_ROT\_AX\_OFFSET\_2
- \$MC\_TRAFO5\_NUTATOR\_AX\_ANGLE\_1 and \$MC\_TRAFO5\_NUTATOR\_AX\_ANGLE\_2
- \$MC\_TRAFO5\_NUTATOR\_VIRT\_ORIAX\_1 and \$MC\_TRAFO5\_NUTATOR\_VIRT\_ORIAX\_2

Transmit transformations

Machine data which are relevant for Transmit transformations:

- \$MC\_TRANSMIT\_BASE\_TOOL\_1 and \$MC\_TRANSMIT\_BASE\_TOOL\_2
- \$MC\_TRANSMIT\_ROT\_AX\_OFFSET\_1 and \$MC\_TRANSMIT\_ROT\_AX\_OFFSET\_2
- \$MC\_TRANSMIT\_ROT\_SIGN\_IS\_PLUS\_1 and \$MC\_TRANSMIT\_ROT\_SIGN\_IS\_PLUS\_2
- \$MC\_TRANSMIT\_POLE\_SIDE\_FIX\_1 and \$MC\_TRANSMIT\_POLE\_SIDE\_FIX\_2
2.4 Activating the transformation MD via part program/softkey (SW 5.2 and later)

- **Tracyl transformations**
  - Machine data which are relevant for Tracyl transformations:
    - $MC_{\text{TRACYL\_BASE\_TOOL\_1}}$ and $MC_{\text{TRACYL\_BASE\_TOOL\_2}}$
    - $MC_{\text{TRACYL\_ROT\_AX\_OFFSET\_1}}$ and $MC_{\text{TRACYL\_ROT\_AX\_OFFSET\_2}}$
    - $MC_{\text{TRACYL\_ROT\_SIGN\_IS\_PLUS\_1}}$ and $MC_{\text{TRACYL\_ROT\_SIGN\_IS\_PLUS\_2}}$

- **Inclined axis transformations**
  - Machine data which are relevant for inclined axes:
    - $MC_{\text{TRAANG\_BASE\_TOOL\_1}}$ and $MC_{\text{TRAANG\_BASE\_TOOL\_2}}$
    - $MC_{\text{TRAANG\_ANGLE\_1}}$ and $MC_{\text{TRAANG\_ANGLE\_2}}$
    - $MC_{\text{TRAANG\_PARALLEL\_VELO\_RES\_1}}$ and $MC_{\text{TRAANG\_PARALLEL\_VELO\_RES\_2}}$
    - $MC_{\text{TRAANG\_PARALLEL\_ACCEL\_RES\_1}}$ and $MC_{\text{TRAANG\_PARALLEL\_ACCEL\_RES\_2}}$

- **Chained transformations**
  - Machine data which are relevant for chained transformations:
    - $MC_{\text{TRACON\_CHAIN\_1}}$ and $MC_{\text{TRACON\_CHAIN\_2}}$

- **Non-specific machine data**
  - Machine data which are not specific to a particular transformation type. They are not uniquely assigned to a particular transformation data set or are relevant even when a transformation is not active:
    - $MC_{\text{X\_AXIS\_IN\_OLD\_X\_Z\_PLANE}}$
    - $MC_{\text{MAX\_LEAD\_ANGLE}}$
    - $MC_{\text{MAX\_TILT\_ANGLE}}$
    - $MC_{\text{ORIENTATION\_IS\_EULER}}$
Supplementary Conditions

3.1 TRANSMIT

Availability

The “TRANSMIT” function is an option with order number: 6FC5 251-0AB01-0AA0.

It is available from product version 2 onwards for:

- SINUMERIK FM-NC with NCU 570
- SINUMERIK 840D with NCU 571–573.
- SINUMERIK 810D

Pole traversal and optimized control response in pole vicinity are available with SW 4.1 and higher.

3.2 TRACYL (peripheral surface transformation)

Availability

The “TRACYL” function is an option with order number: 6FC5 251–0AB01–0AA0.

It is available in SW 2 and later for:

- SINUMERIK FM-NC with NCU 570
- SINUMERIK 840D with NCU 571–573.
- SINUMERIK 810D

3.3 TRAANG (inclined axis)

Availability

The “TRAANG” (inclined axis) function is an option with order number: 6FC5 251–0AB06–0AA0.

It is available in SW 2 and later for:

- SINUMERIK 840D with NCU 572–573.2.
- SINUMERIK 810D
3.4 Chained transformation (SW 5)

**SW 5 and higher**

Two transformations can be chained. However, not just any transformation can be chained to another one. In SW 5 the following restrictions apply:

- The first transformation in the chain must be:
  - an orientation transformation
  - Transmit or
  - side line transformation or
  - inclined axis

- The second transformation must be an **inclined** axis transformation.

- Only two transformations may be chained.

It is permissible (e.g. for testing purposes) to enter only one transformation in the chain list.
## 4.1 Channel-specific machine data

<table>

</thead>
<tbody>
<tr>
<td>22534</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Default value: 0  Min. input limit: 0  Max. input limit: 99999999

Changes effective after:  Protection level: 2/7  Unit: –

Significance: Number of M code that is output at the VDI interface in the case of a transformation changeover on the geometry axes. No M code is output if this MD is set to one of the values 0 to 6, 17 or 30. It is not monitored whether an M code created in this way will conflict with other functions.

## 24110 TRAFO_AXES_IN_1[i]

**MD number**

<table>
<thead>
<tr>
<th>Default value: 1,2,3,4,5,0,0,0</th>
<th>Min. input limit: 1</th>
<th>Max. input limit: [max. no. of channel axes]</th>
</tr>
</thead>
</table>

**Changes effective after**

<table>
<thead>
<tr>
<th>NEWCONFIG (SW 5.2 and higher)</th>
<th>Protection level: 7 / 7 (SW 5.2 and later)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Power On (SW 5.1 and earlier)</td>
<td>2 / 7 (SW 5.1 and earlier)</td>
</tr>
</tbody>
</table>

**Data type:** byte

**Significance:**

Axis assignment at input of 1st transformation

Index i assumes the values 0, 1 and 2 with TRANSMIT.

The assignment for TRANSMIT is:

- \$MC_TRAFO_AXES_IN_1[0]= Channel axis number of axis perpendicular to rotary axis
- \$MC_TRAFO_AXES_IN_1[1]= Channel axis number of rotary axis
- \$MC_TRAFO_AXES_IN_1[2]= Channel axis number of axis parallel to rotary axis

The index entered at the nth position specifies which axis is mapped internally by the transformation on axis n.

**MD irrelevant for ......**

No transformation

**Application**

- $MC_TRAFO_AXES_IN_1[0]=1

**Related to ....**

- TRAFO_AXES_IN_2, TRAFO_AXES_IN_3, ... TRAFO_AXES_IN_8

**References**

- /FB/, F2, "5-Axis Transformation"

## 24120 TRAFO_GEOAX_ASSIGN_TAB_1[i]

**MD number**

<table>
<thead>
<tr>
<th>Default value: 0,0,0</th>
<th>Min. input limit: 0</th>
<th>Max. input limit: [max. no. of channel axes]</th>
</tr>
</thead>
</table>

</tr>
</thead>
<tbody>
<tr>
<td>Power On (SW 5.1 and earlier)</td>
<td>2 / 7 (SW 5.1 and earlier)</td>
</tr>
</tbody>
</table>

**Data type:** byte

**Significance:**

This MD specifies the channel axes on which the axes of the Cartesian coordinate system are mapped when transformation 1 is active.

Index i assumes the values 0, 1, 2 with TRANSMIT. It refers to the first, second and third geometry axis.

**MD irrelevant for ......**

No transformation

**Application**

- $MC_TRAFO_GEOAX_ASSIGN_TAB_1[0]= channel axis number

**Related to ....**

- $MC_AXCONF_GEOAX_ASSIGN_TAB, if no transformation is active.

- **Power On** (SW 5.1 and earlier)

**Protection level:**  
- 7 / 7 (SW 5.2 and later)  
- 2 / 7 (SW 5.1 and earlier)

**Unit:** –

**Data type:** DOUBLE  
Applies from SW version: 2.0

**Significance:**  
Specifies the velocity reserve for jog, positioning and oscillation movements which is held ready on the parallel axis (see `$MC_TRAFO_AXES_IN_n[1]`) for the compensatory movement; MD setting applies to the second TRAANG transformation for each channel.

**Application**  
$MC_TRAANG_PARALLEL_VELO_RES_2=0$

**Related to ....**  
$MC_TRAANG_PARALLEL_VELO_RES_1$

### 24750 TRAANG_ANGLE_2

**MD number**

**Default value:** 0  
Min. input limit: –90  
Max. input limit: 90

**Changes effective after**  
- **NEWCONFIG** (SW 5.2 and higher)  
- **Power On** (SW 5.1 and earlier)

**Protection level:**  
- 7 / 7 (SW 5.2 and later)  
- 2 / 7 (SW 5.1 and earlier)

**Unit:** degrees

**Data type:** DOUBLE  
Applies from SW version: 2.0

**Significance:**  
Specifies the angle of the inclined axis in degrees between the 1st machine axis and the 1st basic axis when TRAANG is active for the second declared TRAANG transformation of the channel. The angle is counted positively in clockwise direction.

**MD irrelevant for ......**  
No TRAANG active

**Application**  
$MC_TRAANG_ANGLE_1=15.0$

**Related to ....**  
TRAANG_ANGLE_1

### 24760 TRAANG_BASE_TOOL_2[i]

**MD number**

**Default value:** 0  
Min. input limit: 0  
Max. input limit: 2

**Changes effective after**  
- **NEWCONFIG** (SW 5.2 and higher)  
- **Power On** (SW 5.1 and earlier)

**Protection level:**  
- 7 / 7 (SW 5.2 and later)  
- 2 / 7 (SW 5.1 and earlier)

**Unit:** mm

**Data type:** DOUBLE  
Applies from SW version: 2.0

**Significance:**  
Specifies the distance of the tool zero point to the appropriate geometry axes for TRAANG active and without tool length compensation being selected. Distance is specified for the 2nd TRAANG transformation for each channel. Programmed length compensations are added to the base tool. Index i assumes values 0, 1, 2 for the 1st to 3rd geometry axis.

**MD irrelevant for ......**  
No TRAANG active

**Application**  
$MC_TRAANG_BASE_TOOL_2[0]=tx$

**Related to ....**  
$MC_TRAANG_BASE_TOOL_1$
### 4.3 Function-specific machine data

#### 24770 TRAANG\_PARALLEL\_ACCEL\_RES\_1

<table>
<thead>

</tbody>
</table>

**Data type:** DOUBLE  
**Applies from SW version:** 2.0

**Significance:** Specifies the axis acceleration reserve for jog, positioning and oscillation movements which is held ready on the parallel axis (see $MC\_TRAFO\_AXES\_IN\_n[1]$) for the compensatory movement; MD setting applies to the second TRAANG transformation for each channel.

**MD irrelevant for:** No TRAANG active

**Application:** $MC\_TRAANG\_PARALLEL\_ACCEL\_RES\_2=0$

**Related to:** TRAANG\_PARALLEL\_ACCEL\_RES\_1
4.3.4 MD for chained transformations

<table>
<thead>
<tr>
<th>24995</th>
<th>TRACON_CHAIN_1[n]</th>
</tr>
</thead>
<tbody>
<tr>
<td>MD number</td>
<td>Transformation chain of the first chained transformation</td>
</tr>
</tbody>
</table>

Default value: 0  
Min. input limit: 0  
Max. input limit: 8  

Changes effective after:  
NEWCONFIG (SW 5.2 and higher)  
Power On (SW 5.1 and earlier)  

Protection level:  
7 / 7 (SW 5.2 and later)  
2 / 7 (SW 5.1 and earlier)  

Data type: DWORD  
Applies from SW version: 5

Significance:  
The MD is saved internally as a table. In the table the numbers of the transformations to be chained are specified in the same sequence as the transformations are to be implemented from the BCS to the MCS. n stands for the index of entries in the MD.

Example:
Optionally, a machine can be operated as a 5-axis machine or as a Transmit machine. A linear axis is not perpendicular to the other linear axes (inclined axis). 5 transformations must be set via machine data, e.g.

<table>
<thead>
<tr>
<th>TRAFO_TYPE_1</th>
<th>16</th>
<th>5-axis transfo, first transformation</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRAFO_TYPE_2</td>
<td>256</td>
<td>Transmit, second transformation</td>
</tr>
<tr>
<td>TRAFO_TYPE_3</td>
<td>1024</td>
<td>Inclined axis, third transformation</td>
</tr>
<tr>
<td>TRAFO_TYPE_4</td>
<td>8192</td>
<td>First chained transformation, fourth transformation</td>
</tr>
<tr>
<td>TRAFO_TYPE_5</td>
<td>8192</td>
<td>Second chained transformation, fifth transformation</td>
</tr>
</tbody>
</table>

If the 4th transformation is to be the chaining: 5-axis transformation / inclined axis and the 5th transformation is to be the chaining: Transmit / inclined axis, then TRACON_CHAIN_1 (1, 3, 0, 0) is entered in the first table and TRACON_CHAIN_2 (2, 3, 0, 0) in the second table. Detailed notation shown in the example in Section 6.

Entry 0 means no transformation (a 3rd and 4th transformation cannot be chained in SW 5).
The transformations can be assigned (TRAFO_TYPE_1 to TRAFO_TYPE_8) in any sequence. The chained transformations do not have to be the last ones. However, they must be behind all transformations that occur in a transformation chain. In the preceding example, this would mean that, for example, the position of the third and fourth transformation must not be swapped. It would be possible though to define a sixth transformation if it is not to be included in a chained transformation.

However, not just any transformation can be chained to another one. In SW 5 the following restrictions apply:
- The first transformation in the chain must be:
  - an orientation transformation
  - (3, 4, 5-axis transformation, universal milling head),
  - Transmit or
  - side line transformation or
  - inclined axis
- The second transformation must be an inclined axis transformation.
- Only two transformations may be chained.

It is permissible (e.g. for testing purposes) to enter only one transformation in the list.

MD irrelevant for: TRAFOOF

Application: Section 6

Special cases, errors: More than 2 transformations in the chain, 2nd transformation not TRAANG

Related to: MD 24100: TRAFO_TYPE

; Activation of TRACYL(40.0)

; See below for programming in Y and Z

; Return to rotational operation TRAFOOF

### Programming with groove wall compensation

#### Contour

It is possible to produce a groove which is wider than the tool by using address OFFN to program the compensation direction (G41, G42) in relation to the programmed reference contour and the distance of the groove side wall from the reference contour (see Fig. 6-1).

#### Tool radius

The tool radius is automatically taken into account with respect to the groove side wall (see Fig. 6-1). The full functionality of the plane tool radius compensation is available (steady transition at outer and inner corners as well as solution of bottleneck problems).
Example program which leads the tool along path I across path II back to the initial position after transformation selection (machine data see Chapter 4, example X-Y-Z-C kinematics):

```
N1  SPOS=0;  Transfer of spindle to rotary axis mode
N5  G0 X25 Y0 Z105 CC=200 F5000 G64;  Positioning of machine above groove center
N10 TRACYL(40.) ; Transformation selection with ; reference diameter 40 mm
N20 G19 G90;  Machining plane is generated cylinder surface
N30 T1 D1;  Tool selection, can also be positioned before ; TRACYL (..)
N40 G1 X20;  Infeed tool to groove base
N50 OFFN=12.;  Define groove wall distance, must not be ; in a separate line
  ; Approach groove wall
N60 G1 Z100 G42;  TRC selection to approach groove wall
  ; Machining of groove section path I
N70 G1 Z50;  Groove section parallel to cylinder plane
N80 G1 Y10;  Groove section parallel to periphery
```

Fig. 6-1  Groove with wall compensation, cylinder coordinates (simplified sketch)
6.2 TRAANG (Inclined axis)

The following programming example relates to the configuration illustrated in Fig. 6-1 and shows the sequence of main steps required to configure the axes and activate TRAANG.

6.3 Chained transformations

Example

The following elements are determined in the next chapter:

- The general channel configuration
- Single transformations
- Chained transformations consisting of previously defined single transformations
- Activation of single transformations
- Activation of chained transformations

The examples include the following transformations:

1. 5-axis transformation with rotatable tool and axis sequence AB (trafo type 16)
2. Transmit (trafo type 256)
3. Inclined axis (trafo type 1024)
4. Chaining of the 1st and 3rd transformation (trafo type 8192)
5. Chaining of the 2nd and 3rd transformation (trafo type 8192)

### Chained transformations

; 4th TRACON (chaining TRAORI / TRAANG)
$MC\_TRAFO\_TYPE\_4 = 8192

$MC\_TRAFO\_GEOAX\_ASSIGN\_TAB\_4[0] = 2
$MC\_TRAFO\_GEOAX\_ASSIGN\_TAB\_4[1] = 1
$MC\_TRAFO\_GEOAX\_ASSIGN\_TAB\_4[2] = 3

$MC\_TRACON\_CHAIN\_1[0] = 1
$MC\_TRACON\_CHAIN\_1[1] = 3
$MC\_TRACON\_CHAIN\_1[2] = 0

; 5th TRACON (chaining TRANSMIT / TRAANG)
$MC\_TRAFO\_TYPE\_5 = 8192

$MC\_TRAFO\_GEOAX\_ASSIGN\_TAB\_5[0] = 1
$MC\_TRAFO\_GEOAX\_ASSIGN\_TAB\_5[1] = 6
$MC\_TRAFO\_GEOAX\_ASSIGN\_TAB\_5[2] = 3

$MC\_TRACON\_CHAIN\_2[0] = 2
$MC\_TRACON\_CHAIN\_2[1] = 3
$MC\_TRACON\_CHAIN\_2[2] = 0

### Part program (extracts)

Example for an NC program which uses the set transformations:

; Call single transformations

; Tool definition
$TC\_DP1[1,1]=120 ; Tool type
$TC\_DP3[1,1] = 10 ; Tool length

n2 x0 y0 z0 a0 b0 f20000 t1 d1
n4 x20

n30 TRANSMIT ; Switch on Transmit
n40 x0 y20
n50 x-20 y0
n60 x0 y-20
n70 x20 y0
n80 TRAFOOF ; Switch off Transmit

n130 TRAANG(45.) ; Switch on inclined axis transformation, parameter: angle 45°
n140 x0 y0 z20
n150 x-20 z0
n160 x0 z-20
n170 x20 z0

### Note

The above examples assume that the angle of the “inclined axis” can be set on the machine and is set to 0 degrees when the single transformation is activated.
6.3 Chained transformations

; 1st chained transformation
; TRAORI + TRAANG

n230 TRACON(1, 45.) ; 1st of 2 chained transformations
; The previously active transformation TRAANG is automatically deselected
; The parameter for the inclined axis is 45°
n240 x10 y0 z0 a3=-1 C3 =1 oriwks
n250 x10 y20 b3 = 1 c3 = 1
...

; 2nd chained transformation
; TRANSMIT + TRAANG

n330 TRACON(2, 40.) ; 2nd chained transformation
; The parameter for the inclined axis is 40°
n335 x20 y0 z0
n340 x0 y20 z10
n350 x-20 y0 z0
n360 x0 y-20 z0
n370 x20 y0 z0
n380 TRAFOOF ; 2nd chained transformation
...
n1000 M30
6.4 Activating transformation MD via a part program (SW 5.2 and higher)

It would be permissible in the following example to re-configure (write) a machine data affecting the second transformation (e.g. $MC\_TRAFO5\_BASE\_ TOOL\_2[2]$) in block N90, since writing a machine data alone does not activate it. However, if the program remained otherwise unchanged, an alarm would occur in block N130, because an attempt would then be made to modify an active transformation.

Example program:

```
N40 TRAORI(2) ; Select 2nd orientation transformation
N50 X0 Y0 Z0 F20000 T1 T1
N60 A50 B50
N70 A0 B0
N80 X10
N90 $MC\_TRAFO5\_BASE\_ TOOL\_1[2] = 50 ; Overwrite an MD
                  ; of the 1st orientation Transformation
N100 A20
N110 X20
N120 X0
N130 NEWCONF ; Accept newly modified machine data
N140 TRAORI(1) ; Select 1st orientation transformation, MD becomes operative
N150 G19 X0 Y0 Z0
N160 A50 B50
N170 A0 B0
N180 TRAFOOF
N190 M30
```
6.4 Activating transformation MD via a part program (SW 5.2 and higher)

Brief Description

Channel-specific measuring
Channel-specific measuring is available with SW 1 and higher. A trigger event which initiates the measuring operation and defines a corresponding measuring mode is programmed in a part program block. The instructions apply to all axes programmed in this particular block.

Axial measuring
Axial measuring is available with SW 4.1 and higher. A trigger event which initiates a measuring operation is programmed in a part program block. A measuring mode for the measurement is defined together with the axis in which the measurements must be taken.

Measuring cycles
A description of how to handle measuring cycles can be found in

References: /FB III/, Measuring Cycles (M4)

Detailed Description

2.1 Hardware requirements

2.1.1 Suitable probes

General

In order to sense the dimensions of tool and workpiece, a touch trigger probe that outputs a constant signal (not a pulse) on deflection is required.

The sensor must operate virtually bounce-free. Most sensors can be adjusted mechanically to ensure that they operate in this manner.

Different types of probe supplied by a variety of manufacturers are available on the market. Probes are therefore divided into three groups according to the number of directions in which they can be deflected (see figure below).

![Probes](image)

**Fig. 2-1** Probe types

**Table 2-1** Assignment between probe type and application

<table>
<thead>
<tr>
<th>Probe type</th>
<th>Turning machines</th>
<th>Milling and machining centers</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Tool measurements</td>
<td>Workpiece measurements</td>
</tr>
<tr>

<td>X</td>
<td>X</td>
</tr>
<tr>
<td>Bi-directional</td>
<td>_</td>
<td>X</td>
</tr>
<tr>
<td>Mono-directional</td>
<td>_</td>
<td>_</td>
</tr>
</tbody>
</table>
Bi-directional probes must be used on turning machines for workpiece measurements, whereas a mono-probe can also be used for this purpose on milling and machining centers.

**Multi-directional probe (3D)**
This probe type can be used unconditionally for measuring tool and workpiece dimensions.

**Bi-directional probe**
This probe type is applied in the same way as a mono-probe in milling and machining centers. Bi-directional probes can be used to take workpiece measurements on turning machines.

**Mono-directional probe**
This probe type can be used subject to some restrictions to take workpiece measurements on milling and machining centers.

**Spindle position with mono-probe**
To be able to use this probe type on milling and machining centers, it must be possible to position the spindle with NC function SPOS and to transfer the switching signal from the probe over 360° to the receiver station (on machine stator).

The probe must be mechanically aligned in the spindle such that it can take measurements in the following directions when the spindle is positioned at 0 degrees.

<table>
<thead>
<tr>
<th>Spindle position</th>
<th>Measurements at 0 degrees spindle position</th>
</tr>
</thead>
<tbody>
<tr>
<td>X-Y plane G17</td>
<td>Positive X direction</td>
</tr>
<tr>
<td>Z-X plane G18</td>
<td>Positive Z direction</td>
</tr>
<tr>
<td>Y-Z plane G19</td>
<td>Positive Y direction</td>
</tr>
</tbody>
</table>

The measurement takes longer with a mono-probe as the spindle needs to be positioned several times with SPOS in the measuring cycle.
2.1.2 Connection of probe

The probe is connected to the SINUMERIK 840D or 810D system via the I/O device interface X121 located on the front plate of the NCU module.
2.1 Hardware requirements

Fig. 2-3 Interfaces, operating and display elements on SINUMERIK 810D

Connection of probe
## 2.1 Hardware requirements

### Interface

The interface connection for a probe is made via the

- **I/O device interface**

  37-pin D-sub plug connector (X121), a maximum of 2 probes can be connected;

The 24 V load power supply for the binary inputs is also connected to X121.

### Table 2-3 Extract from PIN assignment table for front connector X121

![I/O device interface X1](image-url)

**Fig. 2-5 Example of probe interface connection on FM-NC (NCU 570.2), probe 1**
2.2 Channel-specific measurements

2.2.1 Software requirements

**NC software version**  Channel-specific measuring functionality is available for SW 1 and higher.

**MMC software version**  The “Measurement result display” and “Parameter assignment via input dialog” functions require an MMC SW of 3.2 or higher.

2.2.2 Measuring mode

**MEAS and MEAW measurement commands**  The measuring operation is activated from the part program. A trigger event and a measuring mode are programmed. Two different measuring modes are available:

- **MEAS**: Measurement with deletion of distance-to-go

  Example:
  
  N10 G01 F300 X300 Z200 MEAS=–2
  Trigger event is the falling edge (–) of the second probe (2).

- **MEAW**: Measurement without deletion of distance-to-go

  Example:
  
  N20 G01 F300 X300 Y100 MEAW=1
  Trigger event is the rising edge of the first probe (1).

The measuring job is aborted with RESET or when the program advances to a new block.

**Note**

If a GEO axis is programmed in a measuring block, then the measured values are stored for all current GEO axes.

If an axis which is taking part in a transformation is programmed in a measuring block, then the measured values of all of the axes taking part in this transformation are stored.

**Probe status**  As of SW 4, it is possible to scan the probe status directly in the part program and in synchronized actions.

- $A\_PROBE[n]$ with $n=probe$
- $A\_PROBE[n]=1$: probe deflected
- $A\_PROBE[n]=0$: probe not deflected
2.2.3 Measurement results

Read measurement results in PP

The results of the measurement commands are stored in system data of the NCK and can be read via system variables in the part program.

- **System variable $AC_MEA[<No>]**
  Scan status signal of measurement job.
  <No.> stands for probe (1 or 2)

  The variable is deleted at the beginning of a measurement. As soon as the probe fulfills the activation criterion (rising or falling edge), the variable is set. Execution of the measurement job can thus be checked in the part program.

- **System variable $AA_MM[<Axis>]**
  Access to measurement result in machine coordinate system.
  Read in part program and in synchronized actions.
  <Axis> stands for the name of the measurement axis (X, Y, ...).

- **System variable $AA_MW[axis]**
  Access to measurement result in workpiece coordinate system.
  Read in part program and in synchronized actions.
  <Axis> stands for the name of the measurement axis (X, Y, ...).

**References:** /PAZ/, Programming Guide

PLC service display

The probe is tested functionally by means of an NC program.

The measuring signal can be checked at the end of the program in the diagnostic menu "PLC status".

<table>
<thead>
<tr>
<th>Table 2-5</th>
<th>Status display for measuring signal</th>
</tr>
</thead>
<tbody>
<tr>
<td>Probe 1 deflected</td>
<td>DB10 DB B107.0</td>
</tr>
<tr>
<td>Probe 2 deflected</td>
<td>DB10 DB B107.1</td>
</tr>
</tbody>
</table>

The current measuring status of the axis is displayed by means of the interface signal DB(31–48) DBX62.3.

Bit 3=1: Measurement active
Bit 3=0: Measurement not active

**Note**

This signal can be displayed for all measuring functions and also read in synchronized actions with $AA_MEA[ACT["axis"]$.

**References** /FB2/, S5, Synchronized Actions
2.3 Axial measurement (optional)

A measuring operation can be initiated from both the part program and synchronized actions. A measuring mode, the encoder and up to four trigger events are programmed, the trigger events comprising the probe number (1 or 2) and the activation criterion (rising/falling signal edge).

If the measured values are to be stored from encoder 1 and 2 for each trigger event, then only two trigger events can be programmed.

2.3.1 Software requirements

NC software version  Axial measuring functionality is available as an option for SW 4 and higher.

MMC software version  The “Measurement result display” and “Parameter assignment via input dialog” functions require an MMC SW of 3.2 or higher.

2.3.2 Supplementary conditions

Operating mode changeover  Measurement job from part program  A measurement job activated by a part program is not affected by a changeover in operating mode. However, it is deleted immediately the program advances to a new block.  RESET aborts measurement jobs.

Measurement job from synchronized actions  A measurement job activated by a modal synchronized action is not affected by a changeover in operating mode. The job is modally active beyond block limits.

Block search  Measurement job from part program  The job is not started. No measurement check-back signals are supplied.

Measurement job from synchronized actions  Modal measurement jobs are not activated until the programmed conditions are fulfilled.

REPOS  Measurement job from part program  If a measurement job is currently in progress, it is aborted and restarted again after the REPOS block. If the job had already been completed, it is not started again.

Measurement job from synchronized actions  Activated measurement jobs remain unaffected.
2.3.3 Measuring mode

The measuring mode specifies whether trigger events must be activated in parallel or sequentially in ascending sequence and defines the number of measurements to be taken.

Measuring mode 1
The user can program up to 4 different trigger events in the same position control cycle. The measuring signal edges are evaluated in chronological sequence.

- Up to 2 probes with 2 measuring signal edges each can be programmed for each measurement job. If 2 encoders are used, the number of programmed trigger events is halved.
- Where six-axis modules are installed, measuring mode 1 is imaged on measuring mode 2 internally in the control.
- The traversing velocity must be lower or equal to the shortest distance between 2 identical trigger events in each position control clock cycle.

Note
With this mode, the compensation value which was present when the last measuring signal edge was received is calculated for all measured values.

Measuring mode 2
The user can program up to 4 different trigger events one after the other in the configured sequence. Evaluation of measuring signal edges is activated for one trigger event at a time and takes place in the programmed sequence.

- Trigger events are detected only in the programmed sequence.
- The traversing velocity must be lower or equal to the shortest distance between 2 trigger events in each position control cycle.

Note
The measurement does not work with simulated axes!

Probe status
As of SW 4, it is possible to scan the probe status directly in the part program and in synchronized actions.

$A_PROBE[n] \text{ with } n=\text{probe}$
$A_PROBE[n]==1$: probe deflected
$A_PROBE[n]==0$: probe not deflected
2.3 Axial measurement (optional)

2.3.4 Programming

Axial measurements can be programmed with and without deletion of distance-to-go.

MEASA with deletion of distance-to-go
MEAWA without deletion of distance-to-go

MEASA[axis] = (mode, trigger event 1, trigger event 2, trigger event 3, trigger event 4)

Description of parameters:

- **Axis** : Channel axis name (X, Y, ...)
- **Mode** : Ones decade
  
  0 = Abort measurement job (e.g. for synchronized actions)
  
  1 = Up to 4 trigger events that can be activated simultaneously
  
  2 = Up to 4 trigger events that can be activated sequentially
  
  Error output if the first trigger event is already active
  
  3 = Up to 4 trigger events that can be activated sequentially
  
  **NONE** Error output if the first trigger event is already active, alarms 21700/21703 are suppressed

  Tens decade (= encoder selection)
  
  0/not set = Use active measuring system
  
  1 ; 1st measuring system
  
  2 ; 2nd measuring system (If installed. Otherwise the first measuring system is used, no alarm is output)
  
  3 ; 1st and 2 measuring system

If the measurement is taken using two measuring systems, a maximum of two trigger events may be programmed. The measured values of both encoders are recorded for each of the two trigger events.

- **Trigger event**
  
  1 = rising edge of probe 1
  
  -1 = falling edge of probe 1
  
  2 = rising edge of probe 2
  
  -2 = falling edge of probe 2
Note

MEASA and MEAWA can be programmed in one block.

MEASA cannot be programmed in synchronized actions.

The axes for which MEASA has been programmed are not decelerated until all programmed trigger events have arrived.

Measurement jobs started from a part program are aborted by RESET or when the program advances to a new block.

If MEASA/MEAWA are programmed in the same block as MEAS/MEAW this is refused with alarm 21701.

If a geometry axis is used in a measurement, the measured values are only prepared in the workpiece coordinate system if all geometry axes are programmed with the same measurement task. If a geometry axis is missing from the measurement task, the measured value is only stored in the machine coordinate system and alarm 21702 is output. The same applies to axes involved in a transformation.

If the measurement must start on the probe signal edge (with the position of the probe unknown at the instant measurement commences), the customer must evaluate the probe in the part program. By scanning the probe status, it is generally possible to ensure that the next probe signal edge (positive or negative) detected in the hardware will initiate the measurement job.

```plaintext
if $A_PROBE [1] =1 ; Probe deflected ?
    MEAC [X] = (1,1,–1,1) ; Starts on the first detected negative edge.
else
    MEAC [X] = (1,1,1,–1) ; Starts on the first detected positive edge.
endif.
```

The alarms are described in the online help or in References /DA/, Diagnostic Guide

## 2.3.5 Measurement results

**Measurement results**

The results of the measurement command are stored in NCK system data and can be read in the part program by means of system variables.

- **System variable $AC_MEA[]**
  Scan status signal of measurement job.
  `<No.>` stands for probe (1 or 2)

  The variable is deleted at the beginning of a measurement. As soon as the probe fulfills the activation criterion (rising or falling edge), the variable is set. Execution of the measurement job can thus be checked in the part program.

- **System variable $AA_MM1[axis] to $AA_MM4[axis]**
  Access to measurement result of trigger signal in machine coordinate system. Read in part program and in synchronized actions.
  `<Axis>` stands for the name of the measurement axis (X, Y, ...).

- **System variable $AA_MW1[axis] to $AA_MW4[axis]**
  Access to measurement result of trigger signal in machine coordinate system. Read in part program and in synchronized actions.
  `<Axis>` stands for the name of the measurement axis (X, Y, ...).
2.3 Axial measurement (optional)

Programming

If two measuring systems are used to take the measurement, a maximum of two trigger events may be programmed. The measured values of both encoders are recorded for each of the two trigger events.

One trigger event

$\text{AA\_MM1[axis]} = \text{trigger event 1, measured value from encoder 1}$

$\text{AA\_MM2[axis]} = \text{trigger event 1, measured value from encoder 2}$

Two trigger events

$\text{AA\_MM1[axis]} = \text{trigger event 1, measured value from encoder 1}$

$\text{AA\_MM2[axis]} = \text{trigger event 1, measured value from encoder 2}$

$\text{AA\_MM3[axis]} = \text{trigger event 2, measured value from encoder 1}$

$\text{AA\_MM4[axis]} = \text{trigger event 2, measured value from encoder 2}$

PLC service display

The probe is functionally tested by an NC program.

The measuring signal can be checked at the end of the program in the diagnostic menu “PLC status”.

<td></td>
<td></td>
</tr>
</tbody>
</table>

References:  
/PAZ/, Programming Guide Cycles  
/BNM/, User’s Guide Measuring Cycles
2.3.6 Continuous measurements (cyclic measurements)

All measurements are written to a previously defined FIFO variable. The number of measured values is defined in machine data.

- Correct operation of the function can be guaranteed only with an IPO/position control cycle ratio of $\leq 8:1$.
- The contents of the FIFO memory can be read only once. When measurement results are used more than once, the read-out values must be buffered in the user data.

MEAC

Continuous, axial measurements without deletion of distance-to-go

\[
\text{MEAC}[\text{axis}] = (\text{mode, measurement memory, trigger event 1, trigger event 2, trigger event 3, trigger event 4})
\]

**Description of parameters:**

- **Axis**: Channel axis name (X, Y, ...)
- **Mode**: Ones decade
  - 0 = Abort measurement job (for synchronized actions)
  - 1 = Up to 4 trigger events that can be simultaneously activated (a maximum of 4 signals can be triggered simultaneously in one position controller cycle, but the correct order must be observed)
  - 2 = Up to 4 trigger events that can be activated sequentially (only one signal can be triggered per position controller)
- **Tens decade (= encoder selection)**
  - 0/not enabled = active measuring system
  - 1 = 1. measuring system
  - 2 = 2. measuring system (if installed, the first measuring system is otherwise used, no alarm is generated)
  - 3 = 1. and 2 measuring system

If the measurement is taken using two measuring systems, a maximum of two trigger events may be programmed.

- **Measurement memory**: Number of FIFO
- **Trigger event**: $1 = \text{rising edge of probe 1}$
  - $-1 = \text{falling edge of probe 1}$
  - $2 = \text{rising edge of probe 2}$
  - $-2 = \text{falling edge of probe 2}$

The axial measurement values are available in the machine coordinate system (MCS). They are written to a FIFO variable defined by the user, e.g. $\text{SAC}_{-}\text{FIFO1}$. When two probes are configured to take the measurement, the measured values from the second probe are stored separately in the following FIFO.

The number of measured values is limited by MD 28264: $\text{LEN}_{-}\text{AC}_{-}\text{FIFO}$. Variables $\text{SAC}_{-}\text{MEA}$ and $\text{SAA}_{-}\text{MM}$ are therefore irrelevant.

The values can be read from the FIFO both in the part program and from synchronized actions.
2.3 Axial measurement (optional)

The measurement is active until

- MEAC["axis"]=(0) is programmed
- a FIFO is full
- RESET is pressed or end of program M02/M30 is detected

Endless measuring

In order to implement endless measuring, FIFO values must be read cyclically from the part program. The frequency at which measured values are read from the FIFO memory and processed must correspond to the write rate of the NC. The number of valid entries can be read in a FIFO variable.

In order to achieve a defined number of measured values, the measuring function must be explicitly deselected by the program.

FIFO variable

For definition of FIFO variables, see References: /FB2/, SS, Synchronized Actions
2.4 Measurement accuracy and functional testing

2.4.1 Measurement accuracy

Accuracy

The propagation time of the measuring signal is determined by the hardware used. The delay times for a SIMODRIVE 611D installation are between 3.625µ... 9.625µ plus the reaction time of the probe.

The measurement uncertainty is calculated as follows:

\[ \text{Measurement uncertainty} = \text{measuring signal propagation time} \times \text{traversing velocity} \]

The permissible traversing velocities depend on the number of programmed measuring signal edges and the ratio between the IPO clock cycle and position control cycle.

The correctness of measurement results can be guaranteed only in the case of traversing velocities at which no more than 1 identical and no more than 4 different trigger signals arrive in each position control cycle.

2.4.2 Functional testing of probe

Example of functional test

```
%_N_TEST_PROBE_MPF
;SPATH=/_N_MPF_DIR
;Test program for probe interface
N05  DEF INT MTSIGNAL ;Flag for trigger status
N10  DEF INT ME_NR=1 ;Measuring input number
N20  DEF REAL MEASVALUE_IN_X
N30  G17 T1 D1 ;Preselect tool offset for probe
N40  _ANF: G0 G90 X0 F150 ;Start position and measuring velocity
N50  MEAS=ME_NR G1 X100 ;Measurement at measuring input 1 in X axis
N60  STOPRE
N70  MTSIGNAL=$AC_MEA[1] ;Read software switching signal at 1st measuring input
N80  IF MTSIGNAL == 0 GOTOF _FEHL1 ;Evaluate signal
N90  MEASVALUE_IN_X=$AA_MW[X] ;Read measured value into workpiece dimensions
N95  M0
N100 M02
N110 _FEHL1: MSG ("Probe is not switching!")
N120 M0
N130 M02
```
Supplementary Conditions

Axial measurement functionality is available with SW package 4 and higher.
The function is not contained in the export version SINUMERIK 840DE/810DE.

Note
The Measurement function is currently available only on request for the
SINUMERIK 840Di.

Repeat accuracy

This program allows the measuring scatter (repeat accuracy) of the entire measuring system (machine-probe-signal transmission to NC) to be calculated.

In the example, 10 measurements are taken in the X axis and the measured value recorded in the workpiece coordinates.

It is therefore possible to determine the so-called “random” dimensional deviations which are not subject to any trend.

```plaintext
%_N_TEST_GENAU_MPF;
SPATH=/_N_MPF_DIR
N05 DEF INT SIGNAL, II ;Variable definition
N10 DEF REAL MEASVALUE_IN_X[10]
N15 G17 T1 D1 ;Initial conditions,

Brief Description

The “Software cams” function allows position-dependent cam signals to be output to the PLC as well as to the NCK I/Os (in position control cycle).

The position values at which the signal outputs are set can be defined and altered via setting data.

32 software cam pairs are available. These can be used, for example:

- As reversing signals for hydraulically controlled oscillation axes.
- As limit switches

Note

Software cams can be applied for linear axes and modulo rotary axes.

Detailed Description

2.1 General, applications

General
The “Software cams” function (see Chapter 3) generates position-dependent switching signals for axes that supply an actual position value (machine axes) and for simulated axes. The cam signals can be output to the PLC as well as to the NCK I/Os.

The cam positions at which signal outputs are set can be defined and altered via setting data. The setting data can be read and written via MMC, PLC and part program.

Activation
The “Software cams” function can be activated and used in all operating modes. The function remains active in the event of RESET or EMERGENCY STOP.

Applications
Examples of cam signal applications are as follows:

- To activate protection zones
- To initiate additional movements as a function of position
- As reversing signals for hydraulically controlled oscillation axes.

Axis types
Software cams can be used on linear and modulo rotary axes that are defined as machine axes.

Cam range/cam pair
Cams are always assigned in pairs to axes. A pair consists of a plus and a minus cam. 32 cam pairs are available.

The plus and minus cams each simulate a mechanical cam which is actuated at a defined point (cam position) in a specific approach direction when the axis reaches the cam position.

Cam ranges are assigned to the plus and minus cams as follows:

Cam range plus: All positions ≥ plus cam
Cam range minus: All positions ≤ minus cam
2.2 Cam signals and cam positions

2.2.1 Generation of cam signals

Linear axes

The switching edges of the cam signals are generated as a function of the axis traversing direction:

- The minus cam signal switches from 1 to 0 when the axis traverses the minus cam in the positive axis direction.
- The plus cam signal switches from 0 to 1 when the axis traverses the plug cam in the positive direction.

Both cam signals can be output to the PLC and to the NCK I/Os. Separate output of the plus and minus cam signals makes it easy to detect whether the axis is within or outside the plus or minus cam range.

Fig. 2-1 Software cams for linear axis (minus cam < plus cam)
Note
Position switching signals:
If the axis is positioned exactly on the cam, plus or minus, the defined output "flickers". If it traverses by one increment, the output is clearly zero or one.
"Flickering" of the actual position as it is evaluated causes the signals to flicker in this manner.

Fig. 2-2 Software cams for linear axis (plus cam < minus cam)

Modulo rotary axes
The switching edges of the cam signals are generated as a function of the rotary axis traversing direction:
- The plus cam signal switches from 0 to 1 when the axis traverses the minus cam in a positive axis direction and from 1 back to 0 when it traverses the plus cam.
- The minus cam signal changes level in response to every positive edge of the plus cam signal.

Note
The plus cam response applies under the following condition:
Plus cam – minus cam < 180 degrees
If this condition is not fulfilled or if the minus cam is set to a higher value than the plus cam, then the plus cam signal response is inverted. The response of the minus cam signal remains unchanged.

The signal change of the minus cam makes it possible to detect traversal of the cam even if the cam range is set so small that the PLC cannot detect it reliably.

Both cam signals can be output to the PLC and to the NCK I/Os. Separate output of the plus and minus cam signals makes it easy to detect whether the axis is within or outside the plus or minus cam range.

Fig. 2-3 Software cams for modulo rotary axis (plus cam – minus cam < 180 degrees)
2.2 Cam signals and cam positions

Note

The shortest clock cycle is the servo cycle (MN_SW_CAM_TIMER_FAST-OUT_MASK = "HO", i.e. not a timer-triggered output). The clock frequency for a rotational velocity of 1 rev/40 ms and a servo cycle of 2 ms is 18 degrees/2 ms, resulting in an IPO cycle of 54 degrees/6 ms. The software cams are activated in the IPO cycle and the cam signals output in the servo cycle.

The cams do not therefore switch reliably with a distance of 10 degrees between the plus and minus cams.

With a combined fast output, only the plus cam signal is ever output, i.e. the minus cam acting as a signal edge is not used at the same time. There are two variants of this method:

Cam distance < 180 degrees:
Cam = 1 between minus and plus cams, otherwise 0

Cam distance > 180 degrees:
Cam = 0 between minus and plus cams, otherwise 1

In this instance, therefore, the cam signal should switch to 1 only between 20 and 30 degrees. This cannot be switched (servo cycle too long).

The software cams can only be used up to a certain speed for modulo rotary axes depending on IPO cycle, servo cycle and cam distance. Reliable switching cannot be guaranteed at higher speeds.
2.2 Cam signals and cam positions

2.2.2 Cam positions

Setting cam positions

The cam positions of the plus and minus cams are defined via the following general setting data:

SD 41500: SW_CAM_MINUS_POS_TAB_1[n] Position of minus cams 1–8
SD 41501: SW_CAM_PLUS_POS_TAB_1[n] Position of plus cams 1–8
SD 41502: SW_CAM_MINUS_POS_TAB_2[n] Position of minus cams 9–16
SD 41503: SW_CAM_PLUS_POS_TAB_2[n] Position of plus cams 9–16

In addition, from SW 4.1:

SD 41504: SW_CAM_MINUS_POS_TAB_3[n] Position of minus cams 17–24
SD 41505: SW_CAM_PLUS_POS_TAB_3[n] Position of plus cams 17–24
SD 41506: SW_CAM_MINUS_POS_TAB_4[n] Position of minus cams 25–32
SD 41507: SW_CAM_PLUS_POS_TAB_4[n] Position of plus cams 25–32

Note

Owing to the grouping of cam pairs (eight in each group), it is possible to assign different access authorization levels (e.g. for machine-related and workpiece-related cam positions).

The positions are entered in the machine coordinate system. No check is made with respect to the maximum traversing range.

Measuring system metric/inch

From SW 5 and MD 10260: CONVERT_SCALING_SYSTEM=1 (see /G2/) the cam positions no longer refer to the basic system that is set but to the measuring system set in MD 10270: POS_TAB_SCALING_SYSTEM.

MD 10270: POS_TAB_SCALING_SYSTEM=0: metric
MD 10270: POS_TAB_SCALING_SYSTEM=1: inch

The MD 10270 thus defines the measuring system for position specifications from SD 41500 to SD 41507.

A switchover with G70/G71 or G700/G710 has no effect.

Sensing of cam positions

To set the cam signals, the actual position of the axes is compared to the cam position.

Writing/reading of cam positions

The setting data can be accessed for reading and writing via the MMC, PLC and part program.

Data accessing from the part program is not synchronized with block processing. Synchronization can only be achieved by means of a programmed block preprocessing stop (STOPRE command).

It is possible to read and write the cam positions with FB 2 and FB 3 in the PLC user program.
### Axis/cam assignment

An assignment between a cam pair and a machine axis is made via the general MD: `SW_CAM_ASSIGN_TAB[n]` (assignment of software cams to machine axes).

**Note**

Changes to an axis assignment take effect after the next NCK power-up.

Cam pairs to which no axis is assigned are not active.

A cam pair can only be assigned to one machine axis at a time.

Several cam pairs can be defined for one machine axis.

---

### 2.2.3 Lead/delay times (dynamic cam)

#### Times

To compensate for any delays, it is possible to assign two lead or delay times with additive action to each minus and plus cam for the cam signal output.

The two lead or delay times are entered in a machine data and a setting data.

**Note**

The input of negative time values causes a delay in output of cam signals.

#### Input in machine data

The first lead or delay time is entered in the following general machine data:

- `MD 10460: SW_CAM_MINUS_LEAD_TIME[n]`  
  Lead or delay time on minus cams
- `MD 10461: SW_CAM_PLUS_LEAD_TIME[n]`  
  Lead or delay time on plus cams

For example, the following entries can be made in these machine data:

- Constant internal delay times between actual-value sensing and cam signal output (e.g. as determined by an oscilloscope) or
- Constant external delay times.
The second lead or delay time is entered in the following general setting data:

<table>
<thead>
<tr>
<th>Setting Data ID</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SD 41520</td>
<td>SW_CAM_MINUS_TIME_TAB_1[n] Lead or delay time on minus cams 1–8</td>
</tr>
<tr>
<td>SD 41521</td>
<td>SW_CAM_PLUS_TIME_TAB_1[n] Lead or delay time on plus cams 1–8</td>
</tr>
<tr>
<td>SD 41522</td>
<td>SW_CAM_MINUS_TIME_TAB_2[n] Lead or delay time on minus cams 9–16</td>
</tr>
<tr>
<td>SD 41523</td>
<td>SW_CAM_PLUS_TIME_TAB_2[n] Lead or delay time on plus cams 9–16</td>
</tr>
<tr>
<td>SD 41524</td>
<td>SW_CAM_MINUS_TIME_TAB_3[n] Lead or delay time on minus cams 17–24</td>
</tr>
<tr>
<td>SD 41525</td>
<td>SW_CAM_PLUS_TIME_TAB_3[n] Lead or delay time on plus cams 17–24</td>
</tr>
<tr>
<td>SD 41526</td>
<td>SW_CAM_MINUS_TIME_TAB_4[n] Lead or delay time on minus cams 25–32</td>
</tr>
<tr>
<td>SD 41527</td>
<td>SW_CAM_PLUS_TIME_TAB_4[n] Lead or delay time on plus cams 25–32</td>
</tr>
</tbody>
</table>

Delay times which may change during machining must, for example, be entered in these setting data.
2.3 Output of cam signals

The cam status, i.e. cam signals, can be output to the PLC as well as to the NCK I/Os.

**Activation of cam signal output**

Axis-specific IS “Cam activation” (DB31-62, DBX2.0) is used to activate the output of cam signals of an axis.

**Check-back signal to PLC**

Axis-specific IS “Cams active” (DB31-62, DBX62.0) is sent to the PLC to indicate successful activation of all the cams of an axis.

**Note**

Activation can also be linked to other conditions (e.g. axis referenced, RESET effective) by the PLC user.

2.3.1 Output of cam signals to PLC

The status of the cam signals for all machine axes with activated software cams is output to the PLC.

The status is output in the IPO cycle and is transferred to the PLC asynchronously.

**Minus cam signals**

The status of the minus cam signals is entered in the general IS “Minus cam signals 1 to 32” (DB10, DBX110.0 to 113.7).

**Plus cam signals**

The status of the plus cam signals is entered in the general IS “Plus cam signals 1 to 32” (DB10, DBX114.0 to 117.7).

**Note**

<table>
<thead>
<tr>
<th>If ...</th>
<th>then ...</th>
</tr>
</thead>
<tbody>
<tr>
<td>no measuring system is selected or IS “Cam activation” (DB31-62, DBX2.0) = “0”</td>
<td>the following IS’s are set to “0”:</td>
</tr>
<tr>
<td>- Minus cam signals 1–32 (DB10, DBX110.0–113.7)</td>
<td></td>
</tr>
<tr>
<td>- Plus cam signals 1–32 (DB10, DBX114.0–117.7)</td>
<td></td>
</tr>
<tr>
<td>- Cam active (DB31–62, DBX62.0)</td>
<td></td>
</tr>
</tbody>
</table>
2.3 Output of cam signals

2.3.2 Output of cam signals to NCK I/Os

The cam signals are output to the NCK I/Os in the position control cycle.

The 4 on-board outputs on the NCU and a total of 32 optional external NCK outputs are available as the digital outputs of the NCK I/Os.

References: /FB/, A4, “Digital and Analog NCK I/Os”

Hardware assignment

8 pairs of cams in each case are assigned to the hardware bytes used in the two general machine data

MD 10470: SW_CAM_ASSIGN_FASTOUT_1 Hardware assignment for output of cams 1–8 to the NCK I/Os
MD 10471: SW_CAM_ASSIGN_FASTOUT_2 Hardware assignment for output of cams 9–16 to the NCK I/Os
MD 10472: SW_CAM_ASSIGN_FASTOUT_3 Hardware assignment for output of cams 17–24 to the NCK I/Os
MD 10473: SW_CAM_ASSIGN_FASTOUT_4 Hardware assignment for output of cams 25–32 to the NCK I/Os

Note

It is possible to define one HW byte for the output of 8 minus cam signals and one HW byte for the output of 8 plus cam signals in each machine data.

In addition, the output of the cam signals can be inverted with the two machine data.

If the 2nd byte is not specified (= “0”), then the 8 cams are output as an AND operation of the minus and plus cam signals via the 1st HW byte using the 1st inversion screen form.

Status query in part program

The status of the HW outputs can be read in the part program with main run variable $A_OUT[n]$ (n = no. of output bit).
2.3.3 Higher-precision cam signal output

Switching accuracy

The cam signals are output to the NCK I/Os in the position control cycle. Owing to the time grid of the position control cycle, the switching accuracy of the cam signals is limited as a function of velocity.

In this case: \[ \text{Delta pos} = \text{V}_{\text{act}} \times \text{position control cycle} \]

Parameters

\[ \text{Delta pos}: \quad \text{Switching accuracy (governed by position control cycle)} \]
\[ \text{V}_{\text{act}}: \quad \text{Current axis velocity} \]

Example

\[ \text{V}_{\text{act}} = 20 \text{ m/min}, \text{Pos. contr. cycle} = 4 \text{ ms} \]
\[ \text{Delta pos} = 1.33 \text{ mm} \]
\[ \text{V}_{\text{act}} = 2000 \text{ rev/min}, \text{Pos. contr. cycle} = 2 \text{ ms} \]
\[ \text{Delta pos} = 24 \text{ degrees} \]

Timer-controlled output

A significantly higher degree of accuracy can be achieved by outputting the cam signals independently of the position control cycle using a timer interrupt.

Timer-controlled output to the 4 NCU on-board outputs can be selected for 4 cam pairs in general MD: SW_CAM_TIMER_FASTOUT_MASK (screen form for the output of cam signals via timer interrupts to NCU).

In this case, the minus and plus signals of a cam pair are EXCLUSIVE ORed for output as one signal.

Note

This function works independently of the assignment set in
MD 10470: SW_CAM_ASSIGN_FASTOUT_1 or
MD 10471: SW_CAM_ASSIGN_FASTOUT_2 or
MD 10472: SW_CAM_ASSIGN_FASTOUT_3 or
MD 10473: SW_CAM_ASSIGN_FASTOUT_4.

The on-board byte may not be used more than once at any one time.

Restriction

The following applies to the mutual position of the cam positions:

Only one signal is output on a timer-controlled basis per IPO cycle. If there are signal changes for more than one cam pair in an IPO cycle, then the signals are output on a priority bases:

The cam pair with the lowest number (1 ... 32) determines the instant at which all pending signals are output, i.e. the signal change of the other cam pairs takes place at the same instant in time.
Notes
Supplementary Conditions

Availability of function “Software cams, position switching signals”

This function is an option and available for

- SINUMERIK 840D with NCU 572/573, with SW 2 and higher
- SINUMERIK FM-NC with NCU 570.2, with SW 3.2 and higher
- SINUMERIK 810D, SW 3.2 and higher

Data Descriptions (MD, SD)

Default value: 0  Min. input limit: 0  Max. input limit: 8 or 31
Changes effective after Power On  Protection level: 2/4  Unit: –
Data type: BYTE  Applies from SW version: 2.1 or 4.1

Significance:

This machine data allows one machine axis to be assigned to each of the 16 possible cam pairs (comprising one minus and one plus cam).

When a “0” is entered, the appropriate cam is not processed.

The cam signal output is activated via the axial IS “Cam activation” (DB31-48, DBX2.0).

Index [n] of the machine data addresses the cam pair:

n = 0, 1, …, 31 corresponds to cam pair 1, 2, …, 32

Application

Cam pair 1 must be assigned to machine axis 2 and cam pair 3 to machine axis 4. Cam pair 2 is not to be assigned to any axis.

**SW_CAM_ASSIGN_FASTOUT_1**

**10470**

**MD number**

Hardware assignment for output of cams 1–8 to NCK I/Os

**Default value:** 0

**Min. input limit:** ***

**Max. input limit:** ***

**Changes effective after Power On:**

**Protection level:** 2/4

**Unit:** HEX

**Data type:** DWORD

**Applies from SW version:** 2.1

**Significance:**

The cam signal status can be output to the NCK I/Os as well as to the PLC.

The hardware assignment of the minus and plus cam signals to the digital output bytes used can be made in this machine data for **cam pairs 1–8**.

In addition, the assigned output signals can be inverted with this machine data.

The MD is coded as follows:

- **Bit 0–7:** Number of 1st HW byte used with digital outputs
- **Bit 8–15:** Number of 2nd HW byte used with digital outputs
- **Bit 16–23:** Inverting screen form for writing 1st HW byte used
- **Bit 24–31:** Inverting screen form for writing 2nd HW byte used

If both HW bytes are specified, the 1st byte contains the minus cam signals and the 2nd byte the plus cam signals.

If the 2nd byte is not specified (= 0), then the 8 cams are output as an AND operation of the minus and plus cam signals via the 1st HW byte using the 1st inversion screen form.

The status of the non-inverted output signal for linear axes and for rotary axes with "plus cam – minus cam < 180 degrees" is:

- "1" between minus and plus cams
- "0" outside this range

The status of the non-inverted output signal for rotary axes with "plus cam – minus cam ≥ 180 degrees" is:

- "0" between minus and plus cams
- "1" outside this range

The following must be specified as the byte address for the digital outputs:

1: for on-board byte
2–5: for external bytes

**Application**

The minus cam signals must be output via the on-board byte.

The plus cam signals must be output via byte address 3 on the NCU terminal block.

The following must also be inverted:

- **Minus cam signal 2, 4, 5** (corresponds to bits 1, 3, 4 of 1st HW byte)
- **Plus cam signal 1, 3, 4** (corresponds to bits 0, 2, 3 or 2nd HW byte)

The following must be specified as the byte address for the digital outputs:

- **1:** for on-board byte
- **2–5:** for external bytes

**Application**

see MD: SW_CAM_ASSIGN_FASTOUT_1
### 4.1 General machine data

<table>
<thead>
<tr>
<th>MD number</th>
<th>SW_CAM_TIMER_FASTOUT_MASK</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MD number</td>
<td>Screen form for output of cam signals via timer interrupts to NCU</td>
<td></td>
</tr>
<tr>
<td>Default value: 0</td>
<td>Min. input limit: ***</td>
<td>Max. input limit: ***</td>
</tr>
<tr>
<td>Changes effective after Power On</td>
<td>Protection level: 2/4</td>
<td>Unit: HEX</td>
</tr>
<tr>
<td>Data type: DWORD</td>
<td>Applies from SW version: 2.1</td>
<td></td>
</tr>
</tbody>
</table>

**Significance:**

A timer-controlled output to the 4 on-board outputs of the NCK I/Os can be selected in this machine data for 4 cam pairs.

In this case, the minus and plus signals of a cam pair are EXCLUSIVE ORed for output as one signal.

Meaning for set bit:

Associated cam (minus and plus cam signals EXCLUSIVE ORed) is output via a timer interrupt at one of the 4 on-board outputs of the NCU.

In this case, the cam pair signals are assigned in ascending sequence to on-board outputs 1–4.

This function works independently of the assignment set in MD: SW_CAM_ASSIGN_FASTOUT_1 or MD: SW_CAM_ASSIGN_FASTOUT_2.

**Note:** The on-board byte may not be used several times.

If there is more than one signal change in the IPO cycle for the cam pairs specified in the MD, then the cam pair with the lowest number determines the instant of output. The other signal changes take place at the same time.

**Application**

The signals of cam pairs 2, 5 and 7 must be output on a timer-controlled basis:

- MD: SW_CAM_TIMER_FASTOUT_MASK=’H52’
- Signal for cam pair 2 to on-board output 1 of NCK
- Signal for cam pair 5 to on-board output 2 of NCK
- Signal for cam pair 7 to on-board output 3 of NCK
## 4.2 General setting data

**Protection level**: 7/7

**Unit**: s

**Significance**: A lead or delay time can be assigned to each **plus cam 17–24** in this setting data to compensate for delay times.

The switching edge of the associated cam signal is advanced or delayed by the time value entered.

Positive value: Lead time

Negative value: Delay time

Index [n] of the setting data addresses the cam pair:

n = 0, 1, ... , 7 corresponds to cam pair 17, 18, ... , 24

This setting data is added to MD: SW_CAM_PLUS_LEAD_TIME[n].

Related to .... MD: SW_CAM_PLUS_LEAD_TIME[n] (lead or delay time on plus cams 1–16)
### 41526 SW_CAM_MINUS_TIME_TAB_4[n]

**SD number:** Lead or delay time on minus cams 25–32

<table>
<thead>
<tr>
<th>Default value: 0</th>
<th>Min. input limit: ***</th>
<th>Max. input limit: ***</th>
</tr>
</thead>
<tbody>
<tr>
<td>Changes effective immediately</td>
<td>Protection level: 7/7</td>

<td></td>
</tr>
</tbody>
</table>

**Significance:** A lead or delay time can be assigned to each plus cam 25–32 in this setting data to compensate for lead or delay times.

- The switching edge of the associated cam signal is advanced or delayed by the time value entered.
- Positive value: Lead time
- Negative value: Delay time

Index [n] of the setting data addresses the cam pair:

- n = 8, 9, ..., 15 corresponds to cam pair 25, 26, ..., 32

This setting data is added to MD: SW_CAM_PLUS_LEAD_TIME[n+8].

**Related to:** MD: SW_CAM_PLUS_LEAD_TIME[n] (lead or delay time on plus cams 1–16)
Notes
Signal Description

5.1 Signal overview

### Signals from NCK

- Minus cam signal 1 (DB10, DBX110.0)
- Minus cam signal 32 (DB10, DBX113.7)
- Plus cam signal 1 (DB10, DBX114.0)
- Plus cam signal 32 (DB10, DBX117.7)

### Signal to axis/spindle

- Cam activation (DB31-62, DBX2.0)
- Software cams

### Signal from axis/spindle

- Axis/spindle 1
- Axis/spindle 2
- Axis/spindle 3
- Axis/spindle n
- Cam active (DB31-62, DBX62.0)

Brief Description

The functions specific to punching and nibbling operations comprise the following:

- Stroke control
- Automatic path segmentation
- Rotatable punch and die
- Clamp protection

including their activation and deactivation via language commands.
Detailed Description

2.1 Stroke control

The stroke control is used in the actual machining of the workpiece. The punch is activated via an NC output signal when the position is reached. The punching unit acknowledges its punching motion with an input signal to the NC. No axis may move within this time period. Repositioning takes place after the punching operation.

High-speed signals

“High-speed signals” are used for direct communication between the NC and punching unit. Combined with the punch, they allow a large number of holes to be punched per minute since the punch positioning times are interpreted as machining delays.

PLC signals

PLC interface signals are used for non-time-critical functions such as enabling and monitoring.

2.1.1 High-speed signals

High-speed signals are used to synchronize the NC and punching unit. On the one hand, they are applied via a high-speed output to ensure that the punch stroke is not initiated until the metal sheet is stationary. On the other, they are applied via a high-speed input to ensure that the sheet remains stationary while the punch is active. The high-speed digital inputs and outputs on the control are used to operate the punching unit.

The following diagram shows the signal sequence.
2.1 Stroke control

Note

The diagram illustrates the following:
(a) Axis motion of the machine as a v(t) function
(b) "Stroke activation" signal
(c) "Stroke active" signal

The "Stroke active" signal is high-active for reasons relating to open-circuit monitoring.

The chronological sequence of events for punching and nibbling is controlled by the two signals $A_0$ and $E_0$.

- $A_0$ is set by the NCK and is identical to stroke initiation.
- $E_0$ defines the status of the punching unit and is identical to the "Stroke active" signal.

The signal states characterize and define times $t_1$ to $t_4$ in the following way:

$t_1$  
The motion of the workpiece (metal sheet) in relation to the punch is completed at instant $t_1$. Depending on the criterion defined for stroke activation (see following section "Criteria for stroke initiation"), high-speed output $A_0$ is set for punch initiation $\square$.

$t_2$  
The punching unit signals a punch movement via high-speed input $E_0$ at instant $t_2$. This is triggered by signal $A0 \square$.

For safety reasons, signal $E_0$ is high-active (in the case of an open circuit, "Stroke active" is always set and the axes do not move).

The "Stroke active" signal is not reset again until the tool has moved away from the metal sheet ($t_4$).
The NC reacts to the “Stroke active” signal at instant $t_3$ by cancelling the “Stroke activation” signal \[3\]. From this point in time onwards, the NC is in a waiting state. It simply waits for cancellation of the “Stroke active” signal so it can initiate the next axis motion. The next stroke can be initiated only after signal $A_0$ has disappeared.

The punching operation is complete at instant $t_4$, i.e. the punch has exited from the metal sheet again. The NC reacts to a signal transition in signal $E_0$ by starting an axis motion \[4\]. The reaction of the NC to a signal edge change \[4\] is described in the section headed “Axis start after punching” below.

**Note**

The stroke time is determined by the period $\Delta t_b = t_4 - t_1$. Reaction times at instant $t_4$ between the signal transition of $E_0$ and the start of the axis motion must also be added.

### 2.1.2 Criteria for stroke initiation

**Initiate stroke**

The stroke initiation signal must not be set before it is assured that the axes have reached zero speed. In this way, it can be guaranteed that no relative motion between the punching tool and the metal sheet is taking place on the machining plane while punching is in progress.

The following diagram shows the various criteria that can be applied to stroke initiation.
2.1 Stroke control

The time interval between $t_1$ and $t_2$ is determined by the reaction of the punching unit to setting of output $A_0$. This cannot be altered, but can be utilized as a lead time for minimizing deadtimes. The diagram above shows the default setting with which the output is set when the “Exact stop fine window” is reached (default setting of G group 12 G601). The punch initiation times $t_1'$ and $t_1''$ are programmed by means of G602 and G603 (see table below).

<table>
<thead>
<tr>
<th>If</th>
<th>then</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>G603 is programmed,</td>
<td>stop the interpolation</td>
<td>The interpolation reaches the block end. In this case, the axes continue to move until the overtravel has been traversed, i.e. the signal is output at an appreciable interval before the axes have reached zero speed (see $t_1''$).</td>
</tr>
<tr>
<td>G602 is programmed,</td>
<td>reach the coarse in-position window</td>
<td>The signal is output once the axes have reached the coarse in-position window. If this criterion is selected for stroke initiation output, then the instant of stroke initiation can be varied through the size of interpolation window (see $t_1'$).</td>
</tr>
<tr>
<td>G601 is programmed,</td>
<td>reach the fine in-position window</td>
<td>In this case, it can always be ensured that the machine will have reached a standstill at the instant of punching provided that the axis data are set well. However, this variant also guarantees a maximum deadtime (see $t_1$).</td>
</tr>
</tbody>
</table>

Note:
The initial setting of the G group with G601, G602 and G603 (G group 12) is defined via MD: GCODE_RESET_VALUES[11] (G601 is the default setting)

G603

Depending on velocity and machine dynamics, approximately 3–5 interpolation cycles are processed at the end of interpolation before the axes reach zero speed.

In combination with machine data 26018: NIBBLE_PRE_START_TIME, it is possible to delay, and therefore optimize, the instant between reaching the end of interpolation and setting the high-speed output for “Stroke ON”. 
Apart from MD 26018: NIBBLE_PRE_START_TIME, SD 42402 NIB_PUNCH_PRE_START_TIME is also available. This can be altered from the part program and thus adapted to the punching process depending on the processing status of the part program.

The following delay times apply depending on the value programmed for the setting data:

MD 26018 = 0 → SD 42402 is active.
MD 26018 ≠ 0 → MD 26018 is active.

If the “Punching with dwell time, PDELAYON” is active, then the dwell time programmed in connection with this function is active. Both MD 26018 and SD 42402 are inoperative.

### 2.1.3 Axis start after punching

The start of an axis motion after stroke initiation is controlled via input signal “Stroke ON”.

![Signal chart: Axis start after punching](image)

In this case, the time interval between $t_4$ and $t'_4$ acts as a switching-time-dependent reaction time. It is determined by the interpolation sampling time and the programmed punching/nibbling mode.

**PON/SON**

When the punching unit is controlled by means of PON/SON, the maximum delay time is calculated as $|t'_4 - t_4| = 3 \times \text{interpolation cycle}$.

**PONS/SONS**

If the punch is controlled by means of PONS/SONS, then the delay time is determined by $|t'_4 - t_4| \leq 3 \times \text{position control cycle}$.

(Precondition: Stroke time $(t_4 - t_2) > 4$ interpolation cycles).
2.1.4 PLC signals specific to punching and nibbling

In addition to the signals used for direct stroke control, channel-specific PLC interface signals are also available. These are used both to control the punching process and to display operational states.

The “No stroke enable” signal prevents the NC from initiating any punching operation. The NC waits until the enable signal is available before continuing the part program. The “Stroke suppression” signal allows the part program to be processed without initiating a punching operation (dry run). With active path segmentation, the axes traverse in “Stop and go” mode. The “Delayed stroke” signal activates a delayed stroke output such as that programmable with PDELAYON. The “Manual stroke initiation” signal allows the operator to initiate a punching process (controlled via PLC), even when the part program is not being processed. This signal is acknowledged by the “Acknowledge manual stroke initiation” signal.

**Note**
The signals from/to channel are described in Chapter 5 and are listed in Chapter 7.

2.1.5 Punching and nibbling-specific reactions to standard PLC signals

**“Feed stop” interface signal**

In the case of a “Feed stop” signal, the NC reacts as follows with respect to the stroke control:

- If the signal is detected before instant $t_1$, then stroke initiation is suppressed.
- The next stroke is not initiated until the next start or until the “Feed stop” signal has been cancelled. Machining is then continued as if there had been no interruption. If the signal is detected at instant $t_1$, then the current stroke is completed and the NC then rests in the state characterized by $t_4$. To allow it to respond in this manner, time monitoring of the “Stroke active” and “Stroke initiation” signals is dispensed with.

2.1.6 Signal monitoring

Owing to ageing of the punch hydraulics, overshooting of the punch may cause the “Stroke active” signal to oscillate at the end of a stroke. In such cases, an alarm may be generated depending on machine data 26020: NIBBLE_SIGNAL_CHECK (alarm 22054 “distorted punch signal”).

**Reset response**

In the case of an NC reset, the “Stroke initiation” signal is cancelled immediately even if the acknowledgement via the high-speed input has not arrived. A currently activated stroke cannot be suppressed.
2.2 Activation and deactivation

2.2.1 Language commands

Punching and nibbling functions are activated and deactivated via configurable language commands. These replace the special M functions that were used in earlier systems.

References: /PA/, Programming Guide

Groups

The language commands are arranged in groups as follows:

**Group 35**
The actual punching and nibbling functions are activated and deactivated by means of the following language commands:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PON</td>
<td>Punching ON</td>
</tr>
<tr>
<td>SON</td>
<td>Nibbling ON</td>
</tr>
<tr>
<td>PONS</td>
<td>Punching ON, activation in position controller</td>
</tr>
<tr>
<td>SONS</td>
<td>Nibbling ON, activation in position controller</td>
</tr>
<tr>
<td>SPOF</td>
<td>Punching/nibbling OFF</td>
</tr>
</tbody>
</table>

**Group 36**
This group includes the commands which have only a preparatory character and which determine the real nature of the punching function. These language commands are as follows:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PDELAYON</td>
<td>Punching with delay ON</td>
</tr>
<tr>
<td>PDELAYOF</td>
<td>Punching with delay OFF</td>
</tr>
</tbody>
</table>

Since the PLC normally needs to perform some preliminary tasks with respect to these preparatory functions, they are programmed before the activating commands.

**Group 38**
This group contains the commands for switching over to a second punch interface. It can be used, for example, for a second punching unit or set of hammer shears. A second I/O pair which can be used for punching functionality is defined via machine data.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPIF1</td>
<td>First interface is active</td>
</tr>
<tr>
<td>SPIF2</td>
<td>Second interface is active</td>
</tr>
</tbody>
</table>

**Note**
Only one function at a time can be active within a G code group (similar, for example, to the various interpolation modes G0, G1, G2, G3, etc., which are also mutually exclusive).

**SPOF**
Punching and nibbling OFF
The SPOF function terminates all punching and nibbling functions. In this state, the NCK responds neither to the “Stroke active” signal nor to the PLC signals specific to punching and nibbling functions.
If SPOF is programmed together with a travel command in one block (and in all further blocks if punching/nibbling is not activated with SON or PON), the machine approaches the programmed position without the initiation of a punching operation. SPOF deselects SON, SONS, PON and PONS and is equivalent to a Reset state.

Programming example:

```
N20  G90  X100  SON  Activate punching
N25  X50  SPOF  Deactivate punching,
          Positioning without stroke initiation
```

**SON**

**Nibbling ON**

SON activates the nibbling function and deselects the other functions in G group 35 (e.g. PON).

In contrast to punching, the first stroke is made at the start point of the block with the activating command, i.e. before the first machine motion. SON has a modal action, i.e. it remains active until either SPOF or PON is programmed or until the program end is reached. The stroke initiation is suppressed in blocks without traversing information relating to the axes designated as punching or nibbling axes (typically those in the active plane). If a stroke still needs to be initiated, then one of the punching/nibbling axes must be programmed with a 0 traversing path. If the first block with SON is a block without traversing information of the type mentioned, then only one stroke takes place in this block since the start and end points are identical.

Programming example:

```
N70  X50  SPOF  Positioning without punch initiation
N80  X100 SON  Activate nibbling, initiate a stroke before motion (X=50) and at end of programmed motion (X=100)
```

**SONS**

**Nibbling ON (in position control cycle)**

SONS acts in the same way as SON. The function is activated in the position control cycle, thus allowing time-optimized stroke initiation and an increase in the punching rate per minute.

**PON**

**Punching ON**

PON activates the punching function and deactivates SON. Like SON, PON also has a modal action.

In contrast to SON, however, a stroke is not executed until the end of the block or, in the case of automatic path segmentation, at the end of a path segment. PON has an identical action to SON in the case of blocks which contain no traversing information.

Programming example:

```
N100 Y30  SPOF  Positioning without punch initiation
N110 Y100 PON  Activate punching, initiate punch at end of positioning operation (Y=100)
```
### Punching, Nibbling (N4)

#### 2.2 Activation and deactivation

**PONS**

Punching ON (in position controller)

PONS acts in the same way as PON. For explanation, please refer to SONS.

**PDELAYON**

Punching with delay ON

PDELAYON is a preparatory function. This means that PDELAYON is generally programmed before PON. The punch stroke is output with a delay when the programmed end position is reached. The delay time can be defined in seconds by setting data 42400: PUNCH_DWELLETIME. If the defined value cannot be divided as an integer into the interpolation clock cycle, then it is rounded to the next divisible integer value. The function has a modal action.

**PDELAYOF**

Punching with delay OFF

PDELAYOF deactivates punching with delay function, i.e. the punching process continues normally. PDELAYON and PDELAYOF form a G code group.

Programming example:

```
N170 PDELAYON X100 SPOF Positioning without stroke initiation, activate delayed punch initiation

N180 X800 PON Activate punching. When end position is reached, a punch stroke is output with a delay.

N190 PDELAYOF X700 Deactivate delayed punching, activate normal punch initiation. End of programmed motion.
```

**SPIF1**

Activation of first punch interface

SPIF1 activates the first punch interface, i.e. the stroke is controlled via the first pair of high-speed I/Os (see machine data 26004: NIBBLE_PUNCH_OUTMASK, MD 26006: NIBBLE_PUNCH_INMASK). The first punch interface is always active after a reset or control system power up. If only one interface is used, then it need not be programmed.

**SPIF2**

Activation of second punch interface

SPIF2 activates the second punch interface, i.e. the stroke is controlled via the second pair of high-speed I/Os (see machine data 26004: NIBBLE_PUNCH_OUTMASK, MD 26006: NIBBLE_PUNCH_INMASK).
Programming example:

N170  SPIF1  X100  PON   At the end of the block a stroke is initiated at the first high-speed output. The “Stroke active” signal is monitored at the first input.

N180  X800  SPIF2   The second stroke is initiated at the second high-speed output. The “Stroke active” signal is monitored at the second input.

N190  SPIF1  X700   The first interface is used to control all further strokes.
2.2.2 Compatibility with earlier systems

Use of M functions

As in earlier versions, macro technology allows special M functions to be used instead of language commands (compatibility). The following assignments corresponding to those used in earlier systems apply:

- M20, M23 = SPOF
- M22 = SON
- M25 = PON
- M26 = PDELAYON

Note

The M functions can be configured via machine data. As regards the assignments between the M functions and language commands, it must be noted that the M functions are divided into auxiliary function groups.

Examples

- DEFINE M20 AS SPOF or SPOF
- DEFINE M20 AS SPOF M=20 Punching/nibbling OFF
- DEFINE M20 AS SPOF PDELAYOF Punching/nibbling OFF and delayed punching OFF
- DEFINE M22 AS SON or PdelayON
- DEFINE M22 AS SON M=22 Nibbling ON
- DEFINE M22 AS SON M=22 Nibbling ON with auxiliary function output
- DEFINE M25 AS PON or Punching ON
- DEFINE M25 AS PON M=25 Punching ON with auxiliary function output
- DEFINE M26 AS PDELAYON or Delayed punching
- DEFINE M26 AS PDELAYON M=26 Punching and auxiliary function output

Programming example:

```
N100 X100 M20 Positioning without punch initiation
N110 X120 M22 Activate nibbling, stroke initiation before
                and after motion
N120 X150 Y150 M25 Activate punching,
                stroke initiation at end of motion.
```
2.3 Automatic path segmentation

One of the following two methods can be applied to automatically segment a programmed traversing path:

- Path segmentation with maximum path feed value programmed via language command SPP and
- Path segmentation with a number of segments programmed via language command SPN

Both functions generate sub-blocks independently. In earlier systems, language command SPP <number> corresponds to E <number> and SPN <number> to H <number>. Since addresses E and H now represent auxiliary functions, language commands SPP and SPN are used to avoid conflicts. The new procedure is therefore not compatible with those implemented in earlier systems. Both language commands (SPP and SPN) can be configured.

**Note**

The values programmed with SPP are either mm or inch settings depending on the initial setting (analogous to axes).

The automatic path segmentation function ensures that the path is divided into equidistant sections with linear and circle interpolation.

When the program is interrupted and automatic path segmentation is active (SPP/SPN), the contour can be reentered only at the beginning of the segmented block.

**SPP**

- The automatic path segmentation function SPP divides the programmed traversing path into sections of equal size as a function of the programmed feed path.
- Path segmentation is active only when SON or PON is active. (Exception: MD 26014: PUNCH_PATH_SPLITTING = 1).
- SPP is modally active, i.e. the programmed feed value remains valid until it is programmed again, but it can be suppressed on a block-by-block (non-modal) basis by means of SPN.
- The path segments are rounded off by the control system if required so that a total programmed distance can be divided into an integral number of path sections.
- The feed value unit is either mm/stroke or inch/stroke (depending on axis settings).
- If the programmed SPP value is greater than the traversing distance, then the axis is positioned on the programmed end position without path segmentation.
- SPP = 0, reset or program end delete the programmed SPP value. SPP is not deleted when punching/nibbling is deactivated.
The automatic path segmentation function SPN divides the traversing path into the programmed number of path segments.

SPN is active non-modally and is activated if SON or PON has already been activated. (Exception: MD 26014: PUNCH_PATH_SPLITTING = 1).

Any previously programmed SPP value is suppressed for the block containing SPN, but is re-activated again in the following blocks.

Path segmentation is active for linear and circular interpolation. The interpolation mode remains valid, i.e. circles are traversed in the case of circular interpolation.

If a block contains both SPN (number of strokes) and SPP (stroke path), then the “number of blocks” is activated in the current block while the “stroke path” is activated in all blocks that follow.

Path segmentation is active only in conjunction with punching or nibbling functions. (Exception: MD PUNCH_PATH_SPLITTING = 1).

Any programmed auxiliary functions are output before, during the first or after the last sub-block.

In the case of blocks without traversing information, the same rules apply to programmed SPP and SPN commands as defined for SON and PON, i.e. a stroke is initiated only if an axis motion has been programmed.

### 2.3.1 Operating characteristics with path axes

All axes defined and programmed via machine data PUNCHNIB_AXIS_MASK (26010) are traversed along path sections of identical size with SPP and SPN until the programmed end point is reached. This also applies to rotatable tool axes if programmed. The response can be adjusted for single axes (see below).

#### Example of SPP

<table>
<thead>
<tr>
<th>Block</th>
<th>Command</th>
<th>Axis</th>
<th>SPN</th>
<th>Supplementary conditions</th>
</tr>
</thead>
<tbody>
<tr>
<td>N1</td>
<td>G01</td>
<td>X0</td>
<td>Y0</td>
<td>SPOF  Position without punch initiation</td>
</tr>
<tr>
<td>N2</td>
<td>X75</td>
<td>SPP=25</td>
<td>SON</td>
<td>Nibble at feed value 25 mm; Initiate punch before first motion and after each path segment.</td>
</tr>
<tr>
<td>N3</td>
<td>Y10</td>
<td></td>
<td></td>
<td>Position with reduced SPP value because traversing distance &lt; SPP value and initiate punch after motion.</td>
</tr>
<tr>
<td>N4</td>
<td>X0</td>
<td></td>
<td></td>
<td>Reposition with initiation of punch after every path segment.</td>
</tr>
</tbody>
</table>
2.3 Automatic path segmentation

If the programmed path segmentation is not an integral multiple of the total path, then the feed path is reduced (see following diagram).

**Fig. 2-5** Path segmentation

- **X2/Y2**: Programmed traversing path
- **SPP**: Programmed SPP value
- **SPP’**: Automatically rounded offset path
Example of SPN

The number of path segments per block is programmed via SPN.

A value programmed via SPN takes effect on a non-modal basis for both punching and nibbling applications. The only difference between the two modes is with respect to the first stroke. In the case of nibbling operations, this is executed at the beginning of the first segment. With punching, however, it is executed at the end of the first segment. This means that when n segments are programmed, n strokes are executed with punching operations but n + 1 with nibbling. Furthermore, only one stroke is executed in blocks containing no traversing information, even if several of them are programmed. Should it be necessary to generate several strokes at one specific point, then a corresponding number of blocks without traversing information must be programmed.

N1 G01 X0 Y0 SPOF Position without initiation of punch,
N2 X75 SPN=3 SON Activate nibbling, the whole path
    is divided into 3 segments.
    : Since nibbling is active, a stroke
    : is initiated before the first motion
    : and at the end of each segment.
N3 Y10 SPOF Position without initiation of punch
N4 X0 SPN=2 PON Activate punching, the whole path
    is divided into 2 segments.
    : Since punching is active, the first
    : stroke is initiated at the
    : end of the first segment.

Fig. 2-6
Example

Extract from program

N100 G90 X130 Y75 F60 SPOF  | Position at start point of vertical nibble paths
N110 G91 Y125 SPP=4 SON     | End point dimensions (incremental); feedrate value: 4 mm, activate nibbling
N120 G90 Y250 SPOF          | Absolute dimensioning, Position at start point of horizontal nibble path
N130 X365 SPP=4 SON         | End point dimensions, 4 segments, activate nibbling
N140 X525 SPOF              | Position at start point of inclined nibble path
N150 X210 Y75 SPP=3 SON     | End point dimensions feedrate value: 4 mm, Activate nibbling
N160 X525 SPOF              | Position at start point of nibble path on pitch circle path
N170 G02 G91 X–62.5 Y62.5   | Incremental circular interpolation with interpolation parameters, Activate nibbling
     I0  J62.5 SON            | Positioning
N180 G00 G90 Y300 SPOF      |
2.3.2 Response in connection with single axes

The path of single axes programmed in addition to path axes is distributed evenly among the generated intermediate blocks as standard. In the following example, the additional rotary axis C is defined as a synchronous axis in the system. If this axis is programmed as a “Punch-nibble axis” (via PUNCHNIB_AXIS_MASK = 1 for this axis), then the behavior of the synchronous axis can be varied as a function of machine data PUNCH_PARTITION_TYPE.

Example

N10 G1 PON X10 Y10 C0  
N20 SPP=5 X25 C45  
N30 SPN=3 X35 Y20 I10 J10 C90

PUNCH_PARTITION_TYPE=0 (default setting)

In the above example, the axes behave as standard, i.e. the programmed special axis motions are distributed among the generated intermediate blocks of the active path segmentation function in all interpolation modes. In block N20, the C axis is rotated through 15° in each of the three intermediate blocks. The axis response is the same in block N30, in the case of circular interpolation (three sub-blocks, each with 15° (axis rotation)).
2.3 Automatic path segmentation

**PUNCH_PARTITION_TYPE=1**

In contrast to the behavior described above, here the synchronous axis travels the entire programmed rotation path in the first sub-block of the selected path segmentation function. Applied to the above example, the C axis already reaches the programmed end position (C=45) when it reaches X position X=15. It behaves in the same way in the circular interpolation block below.

![Diagram showing automatic path segmentation](image)

**PUNCH_PARTITION_TYPE=2**

MD=2 is set in cases where the axis must behave as described above (PUNCH_PARTITION_TYPE=1) in linear interpolation mode, but according to the default setting in circular interpolation mode (see 1st case). Given the above example, the axis then behaves as follows: In block N20, the C axis is rotated to C=45°. Each of the following circular blocks rotates the C axis through 15°.
The axis response illustrated in the diagram above can be particularly useful when applied to the axis of a rotatable tool in cases where it is used to place the tool in a defined direction (e.g. tangential) in relation to the contour, but where the tangential control function must not be applied. However, it is not a substitute for the tangential control function since the start and end positions of the rotary axis must always be programmed.

Note
Additional offset motions of special axes (in this case, rotary axis C) are implemented via a zero offset.

If the C axis is not defined as a “Punch-nibble axis”, then the C axis motion path is not segmented in block N30 in the above example nor is a stroke initiated at the block end.

If the functionality described above is to be implemented in a variant not specific to nibbling applications, but with alignment of the special axis, then stroke initiation can be suppressed by PLC interface signal (stroke suppression). (Application example: Alignment of electron beam during welding).

Similar axis operating characteristics can be obtained by setting MD 26014 PUNCH_PATH_SPLITTING to “1”. In this case, the path is segmented irrespective of punching or nibbling functions.
2.4 Rotatable tool

The functions

- “Coupled motion” for synchronous rotation of punch and die and
- “Tangential control” for normal alignment of rotary axes for punching tools in relation to workpiece

can be used on nibbling/punching machines with rotatable punching tool and die to achieve a wide variety of applications for the punch.

Fig. 2-8 Illustration of a rotatable tool axis
2.4.1 Coupled motion of punch and die

Using the standard function “Coupled motion”, it is possible to assign the axis of the die as a coupled motion axis to the rotary axis of the punch.

Activation

The “Coupled motion” function is activated or deactivated with language commands TRAILON or TRAILOF.

References: /FB/, M3 “Coupled Motion”

Example

Example of a typical nibbling machine with rotatable punching tools where C is the punch axis and C1 the die axis

```
TRAILON (C, C1, 1);  // Switch on coupled motion grouping
G01 X100 Y100 C0 PON  // Initiate stroke with C axis and C1 axis position C=0=C1
X150 C45              // Initiate stroke with C axis/C1 axis position C=45=C1

M30
```

Initial setting

No coupled motion groupings are active after power-up. Once the two tool axes have approached the reference point, the coupled-axis grouping is not generally separated again. This can be achieved by activating the coupled-axis grouping once (see above example) and setting machine data 20110 RESET_MODE_MASK, bit 8=1. In this way, the coupled-axis grouping remains active after Reset/part program start or end.

2.4.2 Tangential control

The rotary tool axes on punching/nibbling machines are aligned tangentially to the programmed path of the master axes by means of the tangential control function.

Activation

The “Tangential control” function is activated and deactivated with language commands TANGON or TANGOF respectively.

References: /PA/, Programming Guide, Fundamentals

Mode of operation

The tangential axis is coupled to the interpolation of the master axes. It is therefore not possible to position the axis at the appropriate punching position tangentially to the path independently of velocity. This may lead to a reduction in machining velocity if the dynamics of the rotary axis are unfavorable in relation to those of the master axes. Additional offset angles can be programmed directly via language command TANGON.
2.4 Rotatable tool

Note
If the tool (punch and die) is positioned by 2 separate drives, then the functions “Tangential control” and “Coupled axes” can be used. The tangential control function must be activated first followed by coupled axes.

The tangential control function automatically aligns the punch vertically to the direction vector of the programmed path. The tangential tool is positioned before the first punching operation is executed along the programmed path. The tangential angle is always referred to the positive X axis. A programmed additional angle is added to the calculated angle.

The tangential control function can be used in the linear and circular interpolation modes.

Example
Linear interpolation
The punching/nibbling machine has a rotatable punch and die with separate drives.

```
N2  TANG (C, X, Y, 1, "B")
N5  G0  X10  Y5
N8  TRAILON (C, C1, 1)
N10 Y10  C225  PON  F60
N15 X20  Y20  C45
N20 X50  Y20  C90  SPOF
N25 X80  Y20  SPP=10  SON
N30 X60  Y40  SPOF
N32 TANGON (C, 180)
N35 X30  Y70  SPP=3  PON
N40 G91  C45  X–10  Y–10
N42 TANGON (C, 0)
N45 G90  Y30  SPP=3  SON
N50 SPOF  TANGOF
N55 M2
```

2.5 Protection zones

The “clamping protection zone” function is contained as a subset in the “Protection zones” function. Its purpose is to simply monitor whether clamps and tool could represent a mutual risk.

Note

No by-pass strategies are implemented for cases where the clamp protection is violated.

References: /FB/, A3, “Axis Monitoring, Protection Zones”
### Supplementary Conditions

#### Availability of “Punching and nibbling” function

This function is an option and available for:
- SINUMERIK 840D with NCU 572 and 573, SW 3 and higher

</tr>
</tbody>
</table>

**Default value:** 0  
**Min. input limit:** 0  
**Max. input limit:** plus  
**Changes effective after Power On:**  
**Protection level:** 2 / 7  
**Unit:** –  
**Data type:** DWORD  
**Applies from SW version:** 3.1

**Significance:** This data defines which input byte is to be used for the signal “Stroke active”.
- \(= 1\): On-board inputs (4 high-speed NCK inputs) are used.
- \(= 2, 3, 4, 5\): The external digital NCK inputs are used

**Example:**
- Value: “0000 0001” Stroke active is HIGH active
- Value: “0001 0001” Stroke active is LOW active

**Note:**
This MD is not compatible with earlier SW versions. The HIGH word now acts as an inversion mask. In earlier SW versions (< 3.2), the “Stroke active” signal was always LOW active.

**Related to ....**
NIBBLE_PUNCH_INMASK[n]

**References**
/FB/, A4, Digital and Analog NCK I/Os
The signal is high-active as standard with SW 3.2 and higher, i.e., open-circuit monitoring is implemented. If the signal needs to be low-active, the MD must be set, for example, to a value of “H 0001 0001” for the outboard inputs.
## 26002 PUNCHNIB_ASSIGN_FASTOUT

<table>
<thead>
<tr>
<th>MD number</th>
<th>PUNCHNIB_ASSIGN_FASTOUT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default value: 0</td>
<td>Hardware assignment for output byte with stroke control</td>
</tr>
<tr>
<td>Min. input limit: 0</td>
<td>Max. input limit: plus</td>
</tr>
<tr>
<td>Changes effective after Power On</td>
<td>Protection level: 2 / 7</td>
</tr>
<tr>
<td>Data type: DWORD</td>
<td>Applies from SW version: 3</td>
</tr>
<tr>
<td>Significance:</td>
<td>This data defines which output byte is to be used for the stroke control.</td>
</tr>
<tr>
<td>= 1:</td>
<td>On-board outputs (4 high-speed NCK outputs) are used.</td>
</tr>
<tr>
<td>= 2, 3, 4, 5</td>
<td>The external digital NCK outputs are used</td>
</tr>
<tr>
<td>Related to:</td>
<td>NIBBLE_PUNCH_OUTMASK[n]</td>
</tr>
<tr>
<td>References</td>
<td>/FB/, A4, Digital and Analog NCK I/Os</td>
</tr>
</tbody>
</table>

### Significance:

- **Bit 0**: On-board outputs (4 high-speed NCK outputs) are used.
- **Bits 1 to 5**: External digital NCK outputs are used.

### Example:

If the significance of the bit to be defined must be input, e.g., for the signal **"Initiate stroke"**, only NIBBLE_PUNCH_OUTMASK[0] is relevant. This is used to define the output bit for this signal.

### Application:

- **NIBBLE_PUNCH_OUTMASK[0] = 1** → The first bit (bit 0) is defined
- **NIBBLE_PUNCH_OUTMASK[1] = 4** → The third bit (bit 2) is defined

### Note:

The significance of the bit to be defined must be input. The significance of the bit to be defined must be input. The significance of the bit to be defined must be input. The significance of the bit to be defined must be input. The significance of the bit to be defined must be input. The significance of the bit to be defined must be input. The significance of the bit to be defined must be input. The significance of the bit to be defined must be input.

### Example:

```
Bit: 7 6 5 4 3 2 1 0

Significance: 2^7=128 2^6=64 2^5=32 2^4=16 2^3=8 2^2=4 2^1=2 2^0=1
```

## 26004 NIBBLE_PUNCH_OUTMASK[n]

<table>
<thead>
<tr>
<th>MD number</th>
<th>NIBBLE_PUNCH_OUTMASK[n]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default value: see below</td>
<td>Screen form for high-speed output bits</td>
</tr>
<tr>
<td>Min. input limit: 0</td>
<td>Max. input limit: 128</td>
</tr>
<tr>
<td>Changes effective after Power On</td>
<td>Protection level: 2 / 7</td>
</tr>
<tr>
<td>Data type: BYTE</td>
<td>Applies from SW version: 3</td>
</tr>
</tbody>
</table>

### Significance:

A total of 8 byte screen forms for the output of high-speed bits can be defined with this data. Two of these are used at the current time. The standard assignment of this data is as follows:

- **NIBBLE_PUNCH_OUTMASK[0] = 1**: First bit for the first punch interface (SPIF1)
- **NIBBLE_PUNCH_OUTMASK[1] = 0**: First punch interface (SPIF2), not available by default
- **NIBBLE_PUNCH_OUTMASK[2] = 0**
- **NIBBLE_PUNCH_OUTMASK[7] = 0**

### Note:

The significance of the bit to be defined must be input.

### Example:

```
Bit: 7 6 5 4 3 2 1 0

Significance: 2^7=128 2^6=64 2^5=32 2^4=16 2^3=8 2^2=4 2^1=2 2^0=1
```

<tr>
<td>Example:</td>
<td>If the first 2 axes are to be defined as the punching/nibbling axes, then &quot;3&quot; must be entered (corresponds to setting of bits 1 and 0).</td>
</tr>
<tr>
<td>PUNCHNIB_AXIS_MASK = 3</td>
<td>The first 2 axes – typically x and y – are punching/nibbling axes.</td>
</tr>
<tr>
<td>PUNCH_NIB_AXIS_MASK = 11</td>
<td>The first 2 axes (typically x and y) and the third axis (e.g. an axis for the rotatable tool) are punching/nibbling axes. In this case, the response of the 3rd axis with automatic path segmentation can be defined via PUNCH_PARTITION_TYPE.</td>
</tr>
<tr>
<td>Independently of the above, this MD also defines whether the path of the A axis must be segmented by means of SPN=+value&gt; if it is programmed without path axes. In addition, this data also allows single path axes to be treated differently in stroke control mode and with path segmentation. To illustrate this option, let us assume that we have a machine with path axes x, y and rotary axis A. However, we do not want the Z axis traversing paths to be segmented into individual sections nor do we want a stroke to be initiated at the end of a block which contains only a Z axis movement. It is possible to achieve the desired response by setting PUNCHNIB_AXIS_MASK = 11. In this case, pure Z movements are not taken into account by the path segmentation function.</td>
<td></td>
</tr>
<tr>
<td>Related to ....</td>
<td>PUNCH_PARTITION_TYPE</td>
</tr>
</tbody>
</table>
### 4.1 Channel-specific machine data

#### PUNCHNIB_ACTIVATION

<table>
<thead>
<tr>
<th>26012</th>
<th>MD number</th>
<th>PUNCHNIB_ACTIVATION</th>
<th>Activation of punching and nibbling functions</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Default value: 1</td>
<td>Min. input limit: 0</td>
<td>Max. input limit:</td>
</tr>
</tbody>
</table>

**Significance:** This MD defines in what way punching and nibbling functions can be activated:
- PUNCHNIB_ACTIVATION = 0: None of the punching or nibbling functions can be activated. The automatic path segmentation is the only exception if it is enabled via MD: PUNCH_PATH_SPLITTING.
- PUNCHNIB_ACTIVATION = 1: The functions are activated via language commands. If M functions are to be used, then they must be programmed using macros.
- PUNCHNIB_ACTIVATION = 2: The M functions are interpreted directly by the software. Language commands can still be used.

Note: This option is intended only as a temporary solution.

**Related to ...**
- PUNCH_PATH_SPLITTING
- NIBBLE_PUNCH_CODE[n]

#### PUNCH_PATH_SPLITTING

<table>
<thead>
<tr>
<th>26014</th>
<th>MD number</th>
<th>PUNCH_PATH_SPLITTING</th>
<th>Activation of automatic path segmentation</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Default value: 0</td>
<td>Min. input limit: 0</td>
<td>Max. input limit:</td>
</tr>
</tbody>
</table>

**Significance:** This machine data defines whether it should be possible to activate the automatic path segmentation function, even if punching-specific functionality is not available.

- PUNCH_PATH_SPLITTING = 0: Automatic path segmentation can only be activated if punching mode is active and is deactivated as soon as punching mode is deactivated.
- PUNCH_PATH_SPLITTING = 1: In this case, automatic path segmentation can be activated for geometry axes even when punching mode is not active.
### 4.1 Channel-specific machine data

#### PUNCH_PARTITION_TYPE

**Behavior of single axes with active automatic path segmentation**

<table>
<thead>
<tr>
<th>MD number</th>
<th>Default value: 0</th>
<th>Min. input limit: 0</th>
<th>Max. input limit:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Changes effective after Power On</td>
<td>Protection level: 2</td>
<td>Unit: –</td>
<td></td>
</tr>
</tbody>
</table>

**Data type:** DWORD  
**Applies from SW version:** 3

**Significance:** This machine data determines how single axes, which are also nibbling axes according to MD: PUNCHNIB_AXIS_MASK, should respond. It is assumed that rotary axis A is defined as the 4th and nibbling axis in addition to the 3 path axes x, y, z. In this case, there are the following options for defining its response with automatic path segmentation and in stroke control mode:

- **PUNCH_PARTITION_TYPE = 0**
  - No special response in the case of automatic path segmentation. If the single axis is programmed together with path axes in one block, then its total traversing path is segmented in accordance with the path axes, i.e. the purely geometric relationship between single axis and path axes is identical to that for non-segmented movements. If the single axis is programmed without path axes, but with SPN=<value>, then the path is segmented according to the programmed SPN value.

- **PUNCH_PARTITION_TYPE = 1**
  - In this case, the path of the single axis is generally (i.e. regardless of the currently active interpolation mode) traversed in the first segment if the axis is programmed together with path axes.

- **PUNCH_PARTITION_TYPE = 2**
  - In this case, the single axis responds to linear interpolation in the same way as described under PUNCH_PARTITION_TYPE = 1, and to all other interpolation modes as described under PUNCH_PARTITION_TYPE = 0.

**Related to:** PUNCHNIB_AXIS_MASK

#### NIBBLE_PRE_START_TIME

**Automatic pre-start time**

<table>
<thead>
<tr>
<th>MD number</th>
<th>Default value: 0</th>
<th>Min. input limit: 0</th>
<th>Max. input limit:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Changes effective after Power On</td>
<td>Protection level:</td>
<td>Unit: –</td>
<td></td>
</tr>
</tbody>
</table>

**Data type:**  
**Applies from SW version:** 3.1

**Significance:** To minimize any dead times due to the reaction time of the punching unit, it is possible to release the stroke before reaching the inposition window of the axes. The reference time for this is the interpolation end. Since there is normally a delay of some interpolation cycles after reaching the interpolation end (depending on the machine dynamics) until the axes reach their true position, the prestart time is a delay time with respect to reaching the interpolation end. The function is therefore coupled to G603 (block change at the end of interpolation). The time can be set via the machine data NIBBLE_PRE_START_TIME. Example: With an interpolation cycle of 5 ms, a stroke shall be released 2 cycles after reaching the interpolation end. In this case, the value 0.010 s must be selected for NIBBLE_PRE_START_TIME. If a value that is not integrally divisible by the set interpolation time is selected, then the stroke is initiated in the interpolation cycle following the set time.

**Related to:**

#### NIBBLE_SIGNAL_CHECK

**Monitoring of input signal**

<table>
<thead>
<tr>
<th>MD number</th>
<th>Default value: 0</th>
<th>Min. input limit: 0</th>
<th>Max. input limit:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Changes effective after Power On</td>
<td>Protection level:</td>
<td>Unit: s</td>
<td></td>
</tr>
</tbody>
</table>

**Data type:** Flowld  
**Applies from SW version:** 3.1

**Significance:** If for example the stroke active signal is set by punch overshoot between the cycles, the interpolation is stopped. Furthermore, it is possible to generate the "Distorted punch signal" message as a function of machine data NIBBLE_SIGNAL_CHECK.

**Related to:**
### 4.1 Channel-specific machine data

<table>
<thead>
<tr>
<th>26008</th>
<th>NIBBLE_PUNCH_CODE[n]</th>
</tr>
</thead>
<tbody>
<tr>
<td>MD number</td>
<td>Definition of M functions (applies only to SW 3.1)</td>
</tr>
<tr>
<td>Default value: see below</td>
<td>Min. input limit: 0</td>
</tr>
<tr>
<td>Changes effective after Power On</td>
<td>Protection level: 2 / 7</td>
</tr>
<tr>
<td>Data type: DWORD</td>
<td>Applies for Software Version 3.1</td>
</tr>
</tbody>
</table>

**Significance:**
This machine data defines the special M functions for punching and nibbling.

<table>
<thead>
<tr>
<th>Default setting</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>NIBBLE_PUNCH_CODE[0] = 0</td>
<td>20 End punching, nibble with M20</td>
</tr>
<tr>
<td>NIBBLE_PUNCH_CODE[1] = 23</td>
<td>23 End punching, nibble with M23</td>
</tr>
<tr>
<td>NIBBLE_PUNCH_CODE[2] = 22</td>
<td>22 Start nibbling</td>
</tr>
<tr>
<td>NIBBLE_PUNCH_CODE[4] = 26</td>
<td>26 Activation of dwell</td>
</tr>
<tr>
<td>NIBBLE_PUNCH_CODE[5] = 122</td>
<td>Start nibbling with leader, stroke control on servo level</td>
</tr>
<tr>
<td>NIBBLE_PUNCH_CODE[6] = 125</td>
<td>Start punching with leader, stroke control on servo level</td>
</tr>
<tr>
<td>NIBBLE_PUNCH_CODE[7] = 0</td>
<td>0 Not used (available soon)</td>
</tr>
</tbody>
</table>

**Special cases, errors, ......**
If MD: PUNCHNIB_ACTIVATION = 2 (M functions are interpreted directly by software), then MD: NIBBLE_PUNCH_CODE[0] = 20 must be set.

**Related to ....**
PUNCHNIB_ACTIVATION
## 4.2 Channel-specific setting data

### 42400

<table>
<thead>
<tr>
<th>SD number</th>
<th>PUNCH_DWELL_TIME</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Dwell</strong></td>
<td></td>
</tr>
</tbody>
</table>

**Default value:** 1.0  
**Min. input limit:** 0  
**Max. input limit:** plus  
**Changes effective immediately**  
**Data type:** DOUBLE  
**Applies from SW version:** 3  
**Significance:** This machine data is used to set the dwell between reaching the position and initiating the stroke movement. The set value is rounded to whole multiples of the interpolation clock cycle (i.e. the value set here may deviate slightly to the dwell actually applied).  
**Related to:** MD T0710:3MN_PROG_SD_RESET_SAVE_TAB

### 42402

<table>
<thead>
<tr>
<th>SD number</th>
<th>NIBPUNCH_PRE_START_TIME</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Pre-start time</strong></td>
<td></td>
</tr>
</tbody>
</table>

**Default value:** 1.0  
**Min. input limit:** 0  
**Max. input limit:** plus  
**Changes effective immediately**  
**Data type:** DOUBLE  
**Applies from SW version:** 3  
**Significance:** This setting data has exactly the same effect as machine data NIBLE_PRE_START_TIME. Its primary purpose is to allow the pre-start time to be altered from the NC program so that it can be adapted to different metal sheet sizes and thicknesses. However, setting data 42402 is effective only when the machine data has been set to zero.  
**Related to:** NIBLE_PRESTART_TIME

Brief Description

In addition to axes for machining, modern machine tools can also be equipped with axes for auxiliary movements, e.g.:

- Axis for tool magazine
- Axis for tool turret
- Axis for workpiece transport
- Axis for pallet transport
- Axis for loader (also multi-axis)
- Axis for tool changer
- Axis for quill/sleeve or steady

Positioning axes

The “Positioning axes” function allows axes for auxiliary motions to be integrated more easily into the control system. The integration of the positioning axes is simpler:

- During programming:
  Programming is performed together with the axes for workpiece machining in the same part program, without having to sacrifice valuable machining time.

- During program testing/startup:
  Program testing and startup is performed simultaneously for all axes.

- During operation:
  Operation and monitoring of the machining process commence simultaneously for all axes.

- During PLC configuring/startup:
  No allowance has to be made on PLC or external computers (PCs) for synchronization between axes for machining and axes for auxiliary movements.

- During system configuration:
  A second channel is not required.
Notes
Detailed Description

In addition to the axes required for machining, a complex modern machine tool can be equipped with further axes for auxiliary movements. The axes for machining a workpiece are known as path axes: within the channel they are guided by the interpolator so that they start simultaneously and accelerate and reach the end point together.

The auxiliary axes include:

- Axis for tool magazine
- Axis for workpiece transport
- Axis for pallet transport
- Axis for loader
- Axis for tool changer
- Axis for quill/sleeve or steady

Many of these axes were previously manipulated hydraulically and triggered by the part program by means of an auxiliary function.

With control of the axis in the NC, the axis can be addressed by name in the part program and the actual position displayed on the screen.

Positioning axes are traversed independently of the path axes with their own dedicated axis-specific feedrate.

Synchronous axes and geometry axes can be traversed non-modally as positioning axes.

Special traversing instructions are provided for positioning axes, i.e. POS[...], POSA[...]

2.1 Selection of positioning axes

When axes are provided for auxiliary movements on a machine tool, the required properties will decide whether the axis is to be

- programmed in a separate part program
  —> see section 2.1.1 “Separate channels”
- programmed in the same part program as the machining process
  —> see section 2.1.2 “Positioning axes”
- triggered exclusively from the PLC during machining
  —> see section 2.1.3 “Concurrent positioning axes”
2.1 Selection of positioning axes

2.1.1 Separate channel

A channel represents a self-contained NC which, with the aid of a part program, can be used to control the movement of axes, spindles and machine functions independently of other channels.

Independence between channels is assured by means of the following provisions:

- One active part program per channel
- Channel-specific signals such as:
  - IS “NC Start” (DB21, ... DBX7.1)
  - IS “NC Stop” (DB21, ... DBX7.3)
  - IS “Reset” (DB21, ... DBX7.7)
- One feedrate override per channel
- One rapid traverse override per channel
- Channel-specific evaluation and display of alarms
  - Channel-specific display, e.g. for:
    - Actual axis positions
    - Active G functions
    - Active help functions
    - Current program block
- Channel-specific testing and channel-specific modification of programs:
  - Single block
  - Dry run (DRY RUN)
  - Block search
  - Program test

Please see the following for more information on channel functionality:

References: /FB/, K1, “Mode Groups, Channels, Program Operation Mode”
2.1.2 Positioning axis

Positioning axes are programmed together with path axes, i.e. with the axes that are responsible for workpiece machining. Instructions for both positioning axes and path axes can be included in the same NC block. Although they are programmed in the same NC block, the path and positioning axes are not interpolated together and do not reach their end point simultaneously (no direct time relationship, see also section 2.2).

The block change depends on the type of positioning axis programmed (see section 2.3).

- **Type 1** The block change occurs when all path and positioning axes have reached their programmed end point.
- **Type 2** The block change occurs when all path axes have reached their programmed end point.

With positioning axes of type 2, it is possible to approach the programmed end position across several block boundaries.

Positioning axes permit movements to be activated from the same machining program and such movements to be synchronized at block limits (type 1) or at explicit points by means of a WAITP command (type 2).

### Independence of path and positioning axes

The mutual independence of path and positioning axes is ensured by the following measures:

- No shared interpolation
- Each positioning axis has a dedicated axis interpolator
- Dedicated feed override for each positioning axis
- Dedicated programmable feedrate
- Dedicated “axis-specific delete distance-to-go” interface signal.
Positioning Axes (P2)

2.1 Selection of positioning axes

**Dependence of positioning axes**

Positioning axes are dependent in the following respects:

- A shared part program
- Starting of positioning axes only at block boundaries in the part program
- No rapid traverse override
- The signals
  - IS “NC Start” (DB21, ... DBX7.1)
  - IS “NC Stop” (DB21, ... DBX7.3)
  - IS “Reset” (DB21, ... DBX7.7)
  - IS “Read-in disable” (DB21, ... DBX6.1)
  
  act on the entire channel and therefore on positioning axes.
- Program-specific and channel-specific alarms also deactivate positioning axes.
- Program control (dry run feed, program test, DRF, ... etc.) also act on positioning axes
- Block search and single block also act on positioning axes
- Group 1 (movement commands with modal effect) of the G functions (G0, G1, G2, etc.) does not apply to positioning axes.

**References**: /PA/, Programming Guide

**Applications**

The following are typical applications for positioning axes:

- Single-axis loaders
- Multi-axis loaders without interpolation (PTP — point-to-point traversing)
- Workpiece feed and transport

Positioning axes are not suitable for multi-axis loaders that require interpolation between the axes (path interpolator).
2.1.3 Concurrent positioning axis

Concurrent positioning axes are positioning axes with the following attributes:

- Activation from the PLC need not take place at block limits, but can be implemented at any time in any operating mode (even when a part program is already being processed in the channel).
- Program command “WAITP” is required to move a concurrent positioning axis from the part program immediately after power ON.
- The part program continues to run uninhibited, even if the concurrent positioning axis has not reached the position defined by the PLC.
- Software Version 4.3 and higher
  Depending on the machine data AUTO_GET_TYPE, using the programming command
  - “GET(<axis>)” or “WAITP(<axis>)” from the part program it is possible to traverse a concurrent positioning axis again as a channel axis, or using
  - “RELEASE (<axis>)” or “WAITP(<axis>)” to traverse a channel axis as concurrent positioning axis.

Activation from PLC

The concurrent positioning axis is activated via FC 15 or FC 16 from the PLC.

- Feedrate (with feedrate setting of 0, the feed set in MD 32060: POS_AX_Velo (reset for positioning axis velocity) is applied.
- Absolute coordinates (G90), incremental coordinates (G91), absolute coordinates along the shortest path for rotary axes (rotary axis name = DC(value))

The following functions are defined:

- Linear interpolation (G01)
- Feedrate in mm/min or degrees/min (G94)
- Exact stop (G09)
- Settable zero offsets currently selected are valid

Applications

Typical applications for concurrent positioning axes include:

- Tool magazines with manual loading and unloading during machining
- Tool magazines with tool preparation during machining
2.2 Motional behavior

**Path interpolator**
Every channel has a path interpolator for a wide range of interpolation modes such as linear interpolation (G01), circular interpolation (G02/G03), spline interpolation, etc.

**Axis interpolator**
In addition to the path interpolator, each channel also has 5 axis interpolators. When a positioning axis is programmed, an axis interpolator is started in the control (with linear interpolation G01).

This axis interpolator runs independently of the path interpolator until the programmed end position of the positioning axis has been reached.

There is no time relationship between the path interpolator and the axis interpolator, nor between the axis interpolators.

The programmed end position of a positioning axis has been reached when the axis reaches the exact stop fine window (G09). Continuous-path mode (G64) is not possible with positioning axes.

2.3 Block change

Positioning axes can be programmed in the NC block individually or in combination with contour axes.

Contour axes and positioning axes are always interpolated separately (path interpolator and axis interpolators) and this causes them to reach their programmed end positions at different times.

There are two types of positioning axis, whose response differs with respect to block change.

- **Type 1** The block change occurs when all path and positioning axes have reached their programmed end point.
- **Type 2** The block change occurs when all path axes have reached their programmed end point.
Positioning axis type 1

Fig. 2-1  Example of block change for positioning axis type 1

Characteristics of positioning axis type 1

- The block change occurs (NC block finished) when all the path and positioning axes have reached their end positions.

- Continuous-path mode (G64) is only possible for path axes if the positioning axes reach their end positions ahead of the path axes (this is not the case in the example in Fig. 2-1).

- Programming with
  \[
  \text{POS(}\text{name}\text{)} = \text{end point } \text{FA(}\text{name}\text{)} = \text{feed}
  \]
  or abbreviated with
  \[
  \text{POSA(}\text{name}\text{)} = \text{end point}
  \]
  in which case the feed set in MD 32060: POS_AX_VELO is applied.

- The programmed instruction is effective on a non-modal basis. The geometry and synchronous axes are separated from the combined path axis and traversed at an axis-specific velocity.
Positioning axis type 2

Characteristics of positioning axis type 2

- The block change occurs (NC block finished) when the path axes have reached their programmed end positions.
- The positioning axes can traverse across several block boundaries to their programmed end positions.
- Since there is no time relationship between “NC block finished” and the point at which type 2 positioning axes reach their programmed end positions, the WAITP coordination command is provided for the synchronization of the positioning axes (see Section 2.6).
- If a positioning axis is reprogrammed before the previous position has been reached, the “axis cannot be repositioned” alarm is issued.
- Programming with
  POSA[name] = end point FA[name] = feed
  or abbreviated with
  POSA[name] = end point
  in which case the feed set in MD 32060: POS_AX_Velo is applied.
- The programmed instruction is effective on a non-modal basis. The geometry and synchronous axes are separated from the combined path axis and traversed at an axis-specific velocity.
2.4 Velocity

The axis-specific velocity limits and acceleration limits are valid for positioning axes.

Positioning axes can be linear axes and rotary axes.

Positioning axes can also be indexing axes, see:

References: /FB/, T1, “Indexing Axes”

Feedrate override

The path and positioning axes have separate feedrate overrides. Each positioning axis can be adjusted by its own axis-specific feed override.

Rapid traverse override

Rapid traverse override applies only to path axes. Positioning axes have no rapid traverse interpolation (only axial linear interpolation G01) and therefore no rapid traverse override.

Feedrate

The positioning axes traverse at the axis-specific feedrate programmed for them. As illustrated in Section 2.2, the feedrate is not influenced by the path axes.

The feedrate is programmed as an axis-specific velocity in units of min/mm, inch/min or degrees/min.

The axis-specific feedrate is always permanently assigned to a positioning axis by the axis name.

If a positioning axis has no programmed feedrate, the control system automatically applies the rate set in axis-specific MD 32060: POS AX VELO (initial setting for positioning axis velocity).

The programmed axis-specific feedrate is active until the end of the program.

Revolutional feedrate

In JOG mode, the response of the axis/spindle is also dependent on the setting in SD 41100: JOG_REV_IS_ACTIVE (revolutional feedrate for active JOG).

- If this setting data is active, an axis/spindle is always traversed at revolutional feedrate MD 32050: JOG_REV_VELO (revolutional feedrate for JOG) or MD 32040: JOG_REV_VELO_RAPID (revolutional feedrate for JOG with rapid traverse override) as a function of the master spindle.

- If the setting data is not active, then the axis/spindle responds as a function of the setting in SD 43300: ASSIG_FEED_PER_REV_SOURCE (revolutional feedrate for positioning axes/spindles).

- If the setting data is not active, then a geometry axis influenced by a frame with rotation responds as a function of on channel-specific setting data SD 42600: JOG_FEED_PER_REV_SOURCE. (In JOG mode, revolutional feedrate for geometry axes on which a frame with rotation is effective).
2.5 Control by PLC

Channels-specific signals

All channel-specific signals act to the same extent on path and positioning axes. The following signals are the only exceptions (see Chapter 5):

- IS “Feedrate override” (DB21, ... DBB4)
- IS “Delete distance-to-go” (DB21, ... DBX6.2)

Axis-specific signals

The following additional signals are available for positioning axes (see Section 5):

- IS “Positioning axis” (DB31, ... DBX76.5)
- F function (feed) for FA positioning axes
- Axis-specific feed override
- IS “Delete distance-to-go” (DB31, ... DBX2.2), axis-specific

Parameters for FC15

When concurrent positioning axes are activated from the PLC, FC15 is called and supplied with the following parameter data:

- Axis name/axis number
- Approach
- Feedrate (with feedrate setting = 0, the feed set in MD 32060: POS_AX_VELO) is applied.
- Absolute coordinates (G90), incremental coordinates (G91), absolute coordinates along the shortest path for rotary axes (rotary axis name = DC(value))

The following functions are defined:

- Linear interpolation (G01)
- Feedrate in mm/min or degrees/min (G94)
- Exact stop (G09)
- Settable zero offsets currently selected are valid
2.6 Programming

Note
The following documentation should be consulted before programming of positioning axes is attempted:

References: /PA/, Programming Guide

The maximum number of positioning axes that can be programmed in a block is limited to five.

Definition
Positioning axes are defined using the following parameters:

- Axis type: positioning axis type 1 or 2
- End point dimensions
- Absolute or incremental dimension for the end position coordinates
- Feedrate for linear axes in [mm/min], for rotary axes in [degrees/min]

Syntax
Positioning axis type 1:

POS[Q1]=200 FA[Q1]=1000; axis Q1 with feedrate 1000 mm/min to position 200

Positioning axis type 2:

POSA[Q2]=300 FA[Q2]=1500; axis Q2 with feedrate 1500 mm/min to position 300

Within a part program, an axis can be a path axis or a positioning axis. Within a movement block, however, each axis must be assigned a unique axis type.

Absolute/incremental dimensions
The end position coordinates are programmed as absolute dimensions (G90) or incremental dimensions (G91):

Absolute dimensions
G90 POS[Q1]=200
G91 POS[Q1]=AC(200)

Incremental dimensions
G91 POS[Q1]=200
G90 POS[Q1]=IC(200)

Coordination
In the case of positioning axes of type 2 (movement beyond block limits), it must be possible to determine in the part program whether the axis has reached its end position. Only then is it possible to reprogram this positioning axis (otherwise an alarm is issued).

The \texttt{WAITP} coordination command is used to query in the part program whether the end position has been reached.

The coordination command \texttt{WAITP} is programmed in a separate block.
An explicit reference must be made to any axis for which the program is to wait.

Example program:

```
N10 G01 G90 X200 F1000  POSA[Q1]=200 FA[Q1]=500
N15 X400
N20 WAITP(Q1); Execution of the program stops automatically until Q1 in position
N25 X600 POS[Q1]=300; Q1 is positioning axis type 1 (feed FA[Q1] from block N10)
N30 X800 Q1=500; Q1 is path axis (path feed F1000 from block N10)
```

**Tool offset**

A tool length compensation for positioning axes can be implemented by means of an axial zero offset, allowing, for example, the positioning path of a loader to be altered. An example where the axial zero offset might be used in place of the tool length compensation is where a loader containing tools of various dimensions has to bypass an obstacle.

**Program end**

The program end (program status selected) is delayed until all axes (path axes + positioning axes) have reached their programmed end points.

### 2.6.1 Programming from external

Traversal at an externally supplied revolutional feedrate can be selected via axial data SD 43300: ASSIGN_FEED_PER_REV_SOURCE, (revolutional feedrate for axes) and channel-specific setting data SD 42600: JOG_FEED_PER_REV_SOURCE in JOG mode. The following settings are possible via the setting data:

- \( >0 \): The machine axis number of the rotary axis/spindle from which the revolutional feedrate shall be derived
- \( -1 \): The revolutional feedrate is derived from the master spindle of the channel in which the axis/spindle is active in each case
- \( 0 \): The function is deselected
2.7 Response with special functions

2.7.1 Dry run feedrate (DRY RUN)

The dry run feedrate is also effective for positioning axes unless the programmed feedrate is larger than the dry run feedrate.

2.7.2 Single block

<table>
<thead>
<tr>
<th>Positioning axis type 1</th>
<th>Single-block mode is effective with positioning axes of type 1.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Positioning axis type 2</td>
<td>Positioning axes of type 2 continue to operate beyond block limits even in single-block mode.</td>
</tr>
</tbody>
</table>
### Supplementary Conditions

There are no supplementary conditions stipulated for this Description of Functions.

### Data Descriptions (MD, SD)

#### 4.1 Axis/spindle-specific machine data

<table>
<thead>
<tr>
<th>MD number</th>
<th>IS_CONCURRENT_POS_AX</th>
</tr>
</thead>
<tbody>
<tr>
<td>30450</td>
<td>Default on RESET: Neutral axis or channel axis</td>
</tr>
<tr>
<td></td>
<td>Default value: 0</td>
</tr>
<tr>
<td></td>
<td>Min. input limit: 0</td>
</tr>
<tr>
<td></td>
<td>Max. input limit: 1</td>
</tr>
<tr>
<td>Changes effective after RESET:</td>
<td>Protection level: 2</td>
</tr>
<tr>
<td></td>
<td>Unit: None</td>
</tr>
<tr>
<td>Data type: BOOLEAN</td>
<td>Applies from SW version: 1.1</td>
</tr>
</tbody>
</table>

**Significance:**
- The axis is a concurrent positioning axis.
- SW 4.3 and higher (not FM-NC):
  - If FALSE: A neutral axis becomes a channel axis again on RESET.
  - If TRUE: A neutral axis remains in the neutral axis state on RESET and a channel axis becomes a neutral axis.

<table>
<thead>
<tr>
<th>MD number</th>
<th>POS_AX_VELO</th>
</tr>
</thead>
<tbody>
<tr>
<td>32060</td>
<td>Initial setting for positioning axis velocity</td>
</tr>
<tr>
<td></td>
<td>Default value: 0</td>
</tr>
<tr>
<td></td>
<td>Min. input limit: 0</td>
</tr>
<tr>
<td></td>
<td>Max. input limit:</td>

</tr>
<tr>
<td></td>
<td>Unit: mm/min, rpm</td>
</tr>
<tr>
<td>Data type: DOUBLE</td>
<td>Applies from SW version: 1.1</td>
</tr>
</tbody>
</table>

**Significance:**
- Where a positioning axis is programmed in the part program without specifying the axis-specific feedrate, the feedrate entered in MD: POS_AX_VELO is automatically used. The feedrate from MD: POS_AX_VELO applies until an axis-specific feedrate is programmed in the part program for this positioning axis.

**MD irrelevant for ......**
- POS_AX_VELO is irrelevant as a positioning axis for all other axis types.

**Special cases, errors, ......**
- If a zero velocity setting is entered in POS_AX_VELO, the positioning axis does not traverse if it is programmed without feed. If a velocity setting is entered in POS_AX_VELO that is higher than the maximum velocity of the axis (MD 32000: MAX_AX_VELO), the velocity is automatically restricted to the maximum rate.

Positioning Axes (P2) 07.96

5.2 Function call

---

### PLC function call FC15

PLC function call FC15 can be used to start concurrent positioning axes from the PLC. The following parameters are passed to the function call:

- Axis name/axis number
- Approach
- Feedrate (with feedrate setting = 0, the feed set in MD 32060: POS_AX_VELO) is applied.
  
  The F value of FC15 is **not** transferred to the axis-specific IS “F function (feedrate) for positioning axis” DB31, ...DBB78-81.

- Absolute coordinates (G90), incremental coordinates (G91), absolute coordinates along the shortest path for rotary axes (rotary axis name = DC(value))

Since each axis is assigned to exactly one channel, the control can select the correct channel from the axis name/axis number and start the concurrent positioning axis on this channel.

**References:** /FB/, P3, “Basic PLC Program”
Example

In the following example, the two positioning axes Q1 and Q2 represent two separate units of movement. There is no interpolation relationship between the two axes. In the example, the positioning axes are programmed as type 1 (e.g. in N20) and type 2 (e.g. in N40).

Program example

```
N10 G90 G01 G40 T0 D0 M3 S1000
N20 X100 F1000 POS[Q1]=200 POS[Q2]=50 FA[Q1]=500
                FA[Q2]=2000
N30              POS[Q2]=80

Brief Description

Definition

When the “Oscillation” function is selected, an oscillation axis oscillates backwards and forwards at the programmed feedrate or a derived feedrate (revolutional feedrate) between two reversal points. Several oscillation axes can be active at the same time.

Oscillation variants

Oscillation functions can be classified according to the axis response at reversal points and with respect to infeed:

- Asynchronous oscillation beyond block limits.
  While the oscillation movement is in progress, other axes can interpolate freely. The oscillation axis can act as the input axis for dynamic transformation or as the master axis for gantry or coupled-motion axes. Oscillation is not automatically linked to the AUTOMATIC mode.

- Oscillation with continuous infeed.
  Infeed can be executed simultaneously in several axes. However, there is no interpolative connection between the infeed and oscillation movements.

- Oscillation with infeed in both reversal points or only in the left-hand or right-hand reversal point. The infeed can be initiated at a programmable distance from the reversal point.

- Sparking-out strokes after oscillation.

Response at reversal points

The change in direction is initiated:

- without the exact stop limit being reached (exact stop fine or coarse)
- after the programmed position is reached or
- after the programmed position is reached and expiry of a dwell.
Control methods

Oscillation movements can be controlled by various methods:

- The oscillation movement and/or infeed can be interrupted by delete distance-to-go.
- The reversal points can be altered via NC program, PLC, MMC, handwheel or directional keys.
- The feedrate velocity of the oscillation axis can be altered through a value input in the NC program, PLC, MMC or via an override. The feedrate can be programmed to be dependent on a master spindle, rotary axis or spindle (revolutional feedrate).

References: /FB/; V1, “Feedrates”

- The oscillation movement can be controlled entirely by the PLC.
Detailed Description

Methods of oscillation control

There are two modes of oscillation:

1. Asynchronous oscillation
   which is active beyond block limits and can also be started from PLC/MMC,
   and

2. Oscillation as controlled by motion-synchronous actions.
   In this case, asynchronous oscillation and an infeed movement are coupled
   with one another via synchronized actions. In this way, it is possible to
   program oscillation with infeed at the reversal points which is active on a
   non-modal basis.
2.1 Asynchronous oscillation

The characteristics of asynchronous oscillation are as follows:

- The oscillation axis oscillates backwards and forwards between reversal points at the specified feedrate until the oscillation movement is deactivated or until there is an appropriate response to a supplementary condition. If the oscillation axis is not positioned at reversal point 1 when the movement is started, then it traverses to this point first.

- Linear interpolation G01 is active for the oscillation axis regardless of the G code currently valid in the program. Alternately, revolutionary feedrate G95 can be activated.

- Asynchronous oscillation is active on an axis-specific basis beyond block limits.

- Several oscillation axes (i.e. maximum number of positioning axes) can be active at the same time.

- During the oscillation movement, axes other than the oscillation axis can be freely interpolated. A continuous infeed can be achieved via a path movement or with a positioning axis. In this case, however, there is no interpolative connection between the oscillation and infeed movements.

- If the PLC does not have control over the axis, then the axis is treated like a normal positioning axis during asynchronous oscillation. In the case of PLC control, the PLC program must ensure via the appropriate stop bits of the VDI interface that the axis reacts in the desired way to VDI signals. These signals include program end, operating mode changeover and single block.

- The oscillation axis can act as the input axis for the transformations (e.g. inclined axis).

References: /FB/, M1, “Transmit/Peripheral Surface Transformation”

- The oscillation axis can act as the master axis for gantry and coupled motion axes.

References: /FB/, G1, “Gantry Axis”

- It is possible to traverse the axis with jerk limitation (SOFT) and/or with knee-shaped acceleration characteristic (as for positioning axes).

- Block-synchronous activation of the oscillation movement is assured via the part program.

- The oscillation movement can likewise be started, influenced and stopped from the PLC/MMC.

- Interpolatory oscillation is not possible (e.g. oblique oscillation).
2.1.1 Influences on asynchronous oscillation

**Setting data**

The setting data required for oscillation can be set with special language commands in the NCK part program, via the MMC and/or the PLC.

**Feed velocity**

The feed velocity for the oscillation axis is selected or programmed as follows:

- The velocity defined for the axis as a positioning axis is used as the feed velocity. This value can be programmed via FA[axis] and has a modal action. If no velocity is programmed, then the value stored in machine data POS_AX_VELO is used (see positioning axes).

- When an oscillation movement is in progress, the feed velocity of the oscillation axis can be altered via setting data. It can be specified via the part program and setting data whether the changed velocity must take effect immediately or whether it should be activated at the next reversal point.

- The feed velocity can be influenced via the override (axial VDI signal and programmable).

- If “Dry run” is active, the dry run velocity setting is applied if it is higher than the currently programmed velocity.

- Velocity overlay/path overlay can be influenced by the handwheel. See also Table 2-1.

**References:** /FB/, H1, “JOG with and without Handwheel”

- The oscillation axis can be moved with revolutional feedrate.

**Revolutional feedrate**

The reversal feed can also be used for oscillation axes.

**Reversal points**

The positions of the reversal points can be entered via setting data before an oscillation movement is started or while one is in progress.

- The reversal point positions can be entered by means of manual traverse (handwheel, JOG keys) before or in the course of an oscillation movement, regardless of whether the oscillation movement has been interrupted or not.

The following applies to alteration of a reversal point position: When an oscillation movement is already in progress, the altered position of a reversal point does not become effective until this point is approached again. If the axis is already approaching the position, the correction will take effect in the next oscillation stroke.
Note

If a reversal point must be altered at the same time as VDI interface signal “Activate DRF” is set, the handwheel signals are applied both to the DRF offset and to the offset of the reversal point, i.e. the reversal point is shifted absolutely by an amount corresponding to twice the distance.

Stop times

A stop time can be programmed via setting data for each reversal point. The setting can be altered in the following blocks of the NC program. It is then effective in block synchronism from the next applicable reversal point. The stop time can be altered asynchronously via setting data. It is then effective from the instant that the appropriate reversal point is next traversed.

The following table explains the motional behavior in the exact stop range or at the reversal point depending on the stop time input.

Table 2-1  Effect of stop time

</tbody>
</table>

Deactivate oscillation

One of the following options can be set for termination of the oscillation movement when oscillation mode is deactivated:

- Termination of oscillation movement at the next reversal point
- Termination of oscillation movement at reversal point 1
- Termination of oscillation movement at reversal point 2

Following this termination process, sparking-out strokes are processed and an end position approached if programmed.

On switchover from asynchronous oscillation to spark-out and during spark-out, the response at the reversal point regarding exact stop corresponds to the response determined by the stop time programmed for the appropriate reversal point. A sparking-out stroke is the movement towards the other reversal point and back. See table:
### 2.1 Asynchronous oscillation

**Note**

Oscillation with motion-synchronous actions and stop times “OST1/OST2”

Once the set stop times have expired, the internal block change is executed during oscillation (indicated by the new distances to go of the axes). The deactivation function is checked when the block changes. The deactivation function is defined according to the control setting for the motional sequence “OSCTRL”.

This dynamic response can be influenced by the feed override.

An oscillation stroke may then be executed before the sparking-out strokes are started or the end position approached.

Although it appears as if the deactivation response has changed, this is not in fact the case.

</tbody>
</table>

**NC language**

The NC programming language allows asynchronous oscillation to be controlled from the part program. The following functions allow asynchronous oscillation to be activated and controlled as a function of the NC program processing.

**Note**

If the setting data are directly written in the part program, then the data change takes effect prematurely with respect to processing of the part program (at the preprocessing time). It is possible to re-synchronize the part program and the oscillation function commands by means of a preprocessing stop (STOPRE).
2.1 Asynchronous oscillation

References:  /PA/, Programming Guide

1. Activate, deactivate oscillation:
   - OS[oscillation axis] = 1; Activate oscillation for oscillation axis
   - OS[oscillation axis] = 0; Deactivate oscillation for oscillation axis

2. End of oscillation:
   - WAITP(oscillation axis)
     Positioning axis command – stops block until oscillation axis is at fine stop and synchronizes preprocessing and main run. The oscillation axis is entered as a positioning axis again and can then be used normally.
     If an axis is to be used for oscillation, then it must be enabled beforehand with a WAITP(axis) call.
     This also applies if oscillation must be initiated from the PLC/MMC. In this case, the WAITP(axis) call is also needed if the axis was programmed beforehand via the NC program. With SW version 3.2 and higher it is possible to select via machine data $MA_AUTO_GET_TYPE, whether WAITP() shall be performed with programming or automatically.

3. Setting reversal points:
   - OSP1[oscillation axis] = position of reversal point 1
   - OSP2[oscillation axis] = position of reversal point 2
     A position is entered into the appropriate setting data in synchronism with the block in the main run and thus remains effective until the setting data is next changed.
   If incremental traversal is active, then the position is calculated incrementally to the last appropriate reversal point programmed in the NC program.

4. Stop times at reversal points
   - OST1[oscillation axis] = stop time at reversal point 1 in [s]
   - OST2[oscillation axis] = stop time at reversal point 2 in [s]
     A stop time is entered into the appropriate setting data in synchronism with the block in the main run and thus remains effective until the setting data is next changed.
The unit for the stop time is identical to the unit selected for the stop time programmed with G04.

5. **Setting feedrate:**

   - \( \text{FA[axis]} = \text{Fvalue} \)
     Positioning axis feedrate.

   The feedrate is transferred to the appropriate setting data in synchronism with the block in the main run. If the oscillation axis is moved with revolutional feedrate, the corresponding dependencies must be indicated as described in Description of Functions V1.

6. **Setting control settings for sequence of movements:**

   - \( \text{OSCTRL[oscillation axis]} = (\text{setting options, resetting options}) \)

   The set options are defined as follows (the reset options deselect the settings):

<table>
<thead>
<tr>
<th>Option value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Stop at next reversal point on deactivation of the oscillation movement (default). Can only be achieved by resetting option values 1 and 2.</td>
</tr>
<tr>
<td>1</td>
<td>Stop at reversal point 1 on deactivation of the oscillation movement</td>
</tr>
<tr>
<td>2</td>
<td>Stop at reversal point 2 on deactivation of the oscillation movement.</td>
</tr>
<tr>
<td>3</td>
<td>On deactivation of oscillation movement, do not approach reversal point unless sparking-out strokes are programmed.</td>
</tr>
<tr>
<td>4</td>
<td>Approach an end position after spark-out process.</td>
</tr>
<tr>
<td>8</td>
<td>If the oscillation movement is terminated by deletion of distance-to-go, the specified sparking-out strokes must then be executed and the end position (if programmed) approached.</td>
</tr>
<tr>
<td>16</td>
<td>If the oscillation movement is terminated by deletion of distance-to-go, the programmed reversal point must be approached on deactivation of the oscillation movement.</td>
</tr>
<tr>
<td>32</td>
<td>Altered feedrate will only take effect from the next reversal point.</td>
</tr>
<tr>
<td>64</td>
<td>If feedrate setting is 0, path overlay is active, or otherwise velocity overlay</td>
</tr>
<tr>
<td>128</td>
<td>For rotary axis DC (shortest path)</td>
</tr>
</tbody>
</table>

**Note**

The option values 0–3 encode the behavior at reversal points at Power OFF. You can choose one of the alternatives 0–3. The other settings can be combined with the selected alternative according to individual requirements. A “+” character can be inserted to create a string of options.

**Example:** The oscillation movement for axis Z must stop at reversal point 1 on deactivation; an end position must then be approached and a newly programmed feedrate take immediate effect; the axis must stop immediately after deletion of distance-to-go.

\( \text{OSCTRL}[Z] = (1+4, 16+32+64) \)
The set/reset options are entered into the appropriate setting data in synchronism with the block in the main run and thus remain effective until the setting data is next changed.

**Note**
First the control evaluates the reset options, then the setting options.

7. **Sparking-out strokes:**
   - OSNSC[oscillation axis] = number of sparking-out strokes
   The number of sparking-out strokes is entered into the appropriate setting data in synchronism with the block in the main run and thus remains effective until the setting data is next changed.

8. **End position to be approached after deactivation of oscillation:**
   - OSE[oscillation axis] = end position of oscillation axis
   The end position is entered into the appropriate setting data in synchronism with the block in the main run and thus remains effective until the setting data is next changed. Option value 4 is set implicitly according to Table 2-3, such that the set end position is approached.

**Chapter 6** gives an example containing all the important elements for asynchronous oscillation.

### 2.1.2 Asynchronous oscillation under PLC control

**Activation**
The function can be selected from the PLC via setting data OSCILL_IS_ACTIVE in all operating modes except for MDA Ref and JOG Ref.

**Settings**
The following criteria can be controlled from the PLC via setting data: Activation and deactivation of oscillation movement, positions of reversal points 1 and 2, stop times at reversal points, feedrate velocity, the options in the reversal points, the number of sparking-out strokes and the end position after deactivation. However, these values can also be set beforehand as a setting data via the MMC directly or via an NC program. These settings remain valid after power ON and the PLC can also start an oscillation movement set in this way directly via setting data OSCILL_IS_ACTIVE (via variable service).

**Supplementary conditions**
A spindle which must act as an axis to execute an oscillation movement started via the PLC must fulfill the conditions required to allow traversal as a positioning axis, i.e. the spindle must, for example, have been switched to the position control (SPOS) beforehand.

The axes always react to the two stop bits of the VDI interface (DBX28.5, DBX28.6) regardless of whether or not they are being controlled by the PLC.
2.1.3 Special reactions during asynchronous oscillation

With PLC control

The PLC program can take over the control of an oscillation axis via VDI signals. These VDI signals also include program end, operating mode changeover and single block. The following VDI interface signals are ignored: feed/spindle stop and NC STOP; the resulting deceleration request is suppressed in the case of delete distance-to-go.

Without PLC control

If the PLC does not have control over the axis, then the axis is treated like a normal positioning axis (POSA) during asynchronous oscillation.

References: /FB/, P2, “Positioning axes”

EMERGENCY STOP

In the event of an EMERGENCY STOP, the axis is decelerated by the servo (by cancellation of servo enable and follow-up). The oscillation movement is thus terminated and must be restarted if necessary.

Delete distance-to-go

Channel-specific delete distance-to-go is ignored. Axial delete distance-to-go:

Without PLC control

If the oscillation axis is not under PLC control, it is stopped by means of a braking ramp.

With PLC control

In this case, deceleration is suppressed and must be initiated by the PLC. The following applies to both cases: After the axis has been stopped, the appropriate reversal point is approached (see OSCILL_CONTROL_MASK, Section 4) and the distance-to-go deleted. The sparking-out strokes are then executed and the end position approached if this has been set such in OSCILL_CONTROL_MASK. The oscillation movement is thus terminated.

Note

During grinding, the calipers can be put into action via axial delete distance-to-go.

Reset

The oscillation movement is interrupted and deselected with a braking ramp. The options selected subsequently are not processed (sparking-out strokes, end point approach).
Special reactions during asynchronous oscillation (continued)

Working area limitation, limit switches

If it is detected during preprocessing that the oscillation movement would violate an active limitation, then an alarm is output and the oscillation movement not started. If the oscillation axis violates a limitation which has been activated in the meantime (e.g. 2nd software limit switch), then the axis is decelerated down along a ramp and an alarm output.

Caution
Protection zones are not effective!

Follow-up mode

There is no difference to positioning axes.

Program end

If the axis is not controlled by the PLC, then the program end is not reached until the oscillation movement is terminated (reaction as for POSA:Positioning beyond block limits).

If the axis is controlled by the PLC, then it continues to oscillate after program end.

Operating mode changeover

The following table shows the operating modes in which oscillation can be implemented. Changeover to an operating mode which allows oscillation does not affect the oscillation movement. Changeover to inadmissible operating modes is rejected with an alarm. It is not possible to traverse an axis in oscillation mode while applying control commands from the NC program or via operator inputs (JOG) simultaneously; an alarm is output if this is attempted. The general rule is that the type of movement first started has priority.

Single-block processing

If the axis is not controlled by the PLC, then it responds to a single block in the same way as a positioning axis (POSA), i.e. it continues the movement.
2.1 Asynchronous oscillation

Override

The override is specified by the

VDI interface

Axial override acts on the oscillation axis.

Programming

The override acts on oscillation axes in the same way as on positioning axes.

Block search

In the case of a block search, the last valid oscillation function is registered and is activated – depending on machine data OSCILL_MODE_MASK – either immediately after NC start (on approach to approach position after block search) or after the approach position has been reached after block search (default setting).

OSCILL_MODE_MASK bit 0:

0 Oscillation starts after approach position is reached
1 Oscillation starts immediately after NC start

REORG

Reversal point 1 is always approached first before oscillation continues.

ASUB

The oscillation movement continues while an ASUB (asynchronous subprogram) is in progress.
2.2 Oscillation controlled by synchronized actions

Principle

An asynchronous oscillation movement is coupled via synchronized actions with an infeed motion and controlled accordingly.

References: /FB/, S5, “Synchronized Actions”

The following description concentrates solely on the motion-synchronous actions associated with the oscillation function.

Functions

The following function complexes can be implemented by means of the language tools described in detail below:

1. Infeed at reversal point (see 2.2.1).
2. Infeed in reversal point range (see 2.2.2).
3. Infeed at both reversal points (see 2.2.3).
4. Stopping oscillation movement at reversal point until infeed is terminated (see 2.2.4).
5. Enable oscillation movement (see 2.2.5).
6. Preventing premature start of partial infeed (see 2.2.6).

![Fig. 2-1 Arrangement of oscillation and infeed axes plus terms](image)

Legend:

- U1  Reversal point 1
- U2  Reversal point 2
- ii1 Reversal range 1
- ii2 Reversal range 2
2.2 Oscillation controlled by synchronized actions

The parameters governing oscillation (see 2.2.7) must be defined before the movement block containing the assignment between the infeed and oscillation axes (see 2.1.1), the infeed definition (POSP) and the motion-synchronous actions:

The oscillation axis is enabled via a WAITP [oscillation axis] (see MD $MA_AUTO_GET_TYPE), allowing the oscillation parameters to be transferred, i.e. into the setting data, simultaneously. The symbolic names, e.g. $SA_REVERSE_POS1 can then be used to program the motion-synchronous actions.

Note

For motion-synchronous actions with $SA_REVERSE_POS values, the comparison values at the time of interpretation are valid. If setting data are modified subsequently, this has no influence.

For motion-synchronous actions with $AA_REVERSE_POS values, the comparison values within interpolation are valid. This ensures a reaction to the modified reversal positions.

- Motion-synchronous conditions WHEN, WHenever
- Activation through motion block
  - Assign oscillation axis and infeed axes to one another OSCILL
  - Specify infeed response POSP.

The elements which have not yet been discussed are explained in more detail in the following sections.
Some examples are described in Chapter 6.

Note

If the condition with which the motion-synchronous action (WHEN and WHENEVER) has been defined is no longer valid, the OVERRIDE for this condition is automatically set to 100% if the OVERRIDE had been set to 0% before.

Main run evaluation

From software version 3.2, it is possible to compare the synchronization conditions in the interpolation cycle in the main run with the current actual values ($S variable on the right of comparison conditions). With normal system variable comparison, the expressions are evaluated in the first run. The complete extended possibilities for synchronized actions are listed in the following documentation:

References: /FB/, S5, “Motion-synchronous actions”.
2.2 Oscillation controlled by synchronized actions

Example 1

Oscillation, reversal position firmly set via setting data:

$\text{SA\_OSCILL\_REVERSE\_POS1}[Z]=-10$
$\text{SA\_OSCILL\_REVERSE\_POS2}[Z]=10$

G0 X0 Z0
WAITP(Z)

ID=1 WHENEVER $\text{AA\_IM}[Z] < \text{SA\_OSCILL\_REVERSE\_POS1}[Z]$ DO
$\text{AA\_OVR}[X]=0$
ID=2 WHENEVER $\text{AA\_IM}[Z] > \text{SA\_OSCILL\_REVERSE\_POS2}[Z]$ DO
$\text{AA\_OVR}[X]=0$

; If the actual value of the oscillation
; axis has exceeded the reversal point,
; the infeed axis is stopped.

OS[Z]=1 FA[X]=1000 POS[X]=40 ; Oscillation on
OS[Z]=0 ; Oscillation off

M30

Example 2

Oscillation with online change of the reversal position, i.e. any modification of
reversal position 1 via the user surface are immediately taken into account with
active oscillation movement.

$\text{SA\_OSCILL\_REVERSE\_POS1}[Z]=-10$
$\text{SA\_OSCILL\_REVERSE\_POS2}[Z]=10$

G0 X0 Z0
WAITP(Z)

ID=1 WHENEVER $\text{AA\_IM}[Z] < \text{SA\_OSCILL\_REVERSE\_POS1}[Z]$ DO
$\text{AA\_OVR}[X]=0$

M30
2.2 Oscillation controlled by synchronized actions

2.2.1 Infeed at reversal point 1 or 2

Function
As long as the oscillation axis has not reached the reversal point, the infeed axis does not move.

Application
Direct infeed in reversal point

Programming
For reversal point 1:
WHENEVER $AA_IM[Z] <> $SA_OSCILL_REVERSE_POS1[Z] DO
$AA_OVR[X] = 0 $AA_OVR[Z] = 100

For reversal point 2:
WHENEVER $AA_IM[Z] <> $SA_OSCILL_REVERSE_POS2[Z] DO
$AA_OVR[X] = 0 $AA_OVR[Z] = 100

Explanation of system variables:
$AA_IM[Z] Actual position of oscillation axis Z in Machine coordinate system
$SA_OSCILL_REVERSE_POS1[Z] Position of reversal point 1 of oscillation axis
$AA_OVR[X] Axial override of infeed axis
$AA_OVR[Z] Axial override of oscillation axis

Explanation of keywords:
WHENEVER ... DO ... Whenever condition is fulfilled, then ....

Infeed
The absolute infeed value is defined by instruction POSP.
See 2.2.8

Assignment
The assignment between the oscillation axis and the infeed axis is defined by instruction OSCILL.
See 2.2.7

2.2.2 Infeed in reversal point range

Function
Reversal point range 1:
No infeed takes place provided the oscillation axis has not reached the reversal point range (position at reversal point 1 plus contents of variable ii1). This applies on the condition that reversal point 1 is set to a lower value than reversal point 2. If this is not the case, then the condition must be changed accordingly.

Application
Reversal point range 1:
The purpose of the synchronized action is to prevent the infeed movement from starting until the oscillation movement has reached reversal point range 1.
See Fig. 2-1.
2.2 Oscillation controlled by synchronized actions

Programming

Reversal point range 1:

WHENEVER $AA_{IM}[Z] > $SA_{OSCILL\_REVERSE\_POS1}[Z] + ii1 DO

$AA_{OVR}[X] = 0

Explanation of system variables:

$AA_{IM}[Z]$ Actual position of oscillation axis Z

$SA_{OSCILL\_REVERSE\_POS1}[Z]$ Position of reversal point 1 of oscillation axis

$AA_{OVR}[X]$ Axial override of infeed axis

ii1 Size of reversal range (user variable)

Explanation of keywords:

WHENEVER ... DO ... Whenever condition is fulfilled, then ....

Function

Reversal point range 2:

The infeed axis stops until the current position (value) of the oscillation axis is lower than the position at reversal point 2 minus the contents of variable ii2. This applies on condition that the setting for reversal point position 2 is higher than that for reversal point position 1. If this is not the case, then the condition must be changed accordingly.

Application

Reversal point range 2:

The purpose of the synchronized action is to prevent the infeed movement from starting until the oscillation movement has reached reversal point range 2. See Fig. 2-1.

Programming

Reversal point range 2:

WHENEVER $AA_{IM}[Z] < $SA_{OSCILL\_REVERSE\_POS2}[Z] – ii2 DO

$AA_{OVR}[X] = 0

Explanation of system variables:

$AA_{IM}[Z]$ Actual position of oscillation axis Z

$SA_{OSCILL\_REVERSE\_POS2}[Z]$ Position of reversal point 2 of oscillation axis

$AA_{OVR}[X]$ Axial override of infeed axis

ii2 Size of reversing point range 2 (user variable)

Infeed

The absolute infeed value is defined by instruction POSP.

See 2.2.8.

Assignment

The assignment between the oscillation axis and the infeed axis is defined by instruction OSCILL.

See 2.2.7.
## 2.2.3 Infeed at both reversal points

**Principle**

The functions described above for infeed at the reversal point and in the reversal point range can be freely combined.

**Combinations**

<table>
<thead>
<tr>
<th>Infeed:</th>
</tr>
</thead>
<tbody>
<tr>
<td>at U1 at U2</td>
</tr>
<tr>
<td>at U1 range U2</td>
</tr>
<tr>
<td>range U1 at U2</td>
</tr>
<tr>
<td>range U1 range U2</td>
</tr>
</tbody>
</table>

**One-sided infeed**

at U1

at U2

range U1

range U2

These options are described in Sections 2.2.1 and 2.2.2.
2.2 Oscillation controlled by synchronized actions

2.2.4 Stopping oscillation movement at reversal point

Function

Reversal point 1:
Every time the oscillation axis reaches reversal position 1, it must be stopped by means of the override and the infeed movement started.

Application
The synchronized action is used to hold the oscillation axis stationary until part infeed has been executed. This synchronized action can be omitted if the oscillation axis need not wait at reversal point 1 until part infeed has been executed. At the same time, this synchronized action can be used to start the infeed movement if this has been stopped by a previous synchronized action which is still active.

Programming
WHENEVER $AA_IM[oscillation axis] == $SA_OSCILL_REVERSE_POS1[oscillation axis]
DO $AA_OVR[oscillation axis] = 0   $AA_OVR[infeed axis] = 100

Explanation of system variables:
$AA_IM[oscillation axis] Current position of oscillation axis
$SA_OSCILL_REVERSE_POS1[oscillation axis] Reversal point 1 of oscillation axis
$AA_OVR[oscillation axis] Axial override of oscillation axis
$AA_OVR[infeed axis] Axial override of infeed axis

Function

Reversal point 2:
Every time the oscillation axis reaches reversal position 2, it must be stopped by means of override 0 and the infeed movement started.

Application
The synchronized action is used to hold the oscillation axis stationary until part infeed has been executed. This synchronized action can be omitted if the oscillation axis need not wait at reversal point 2 until part infeed has been executed. At the same time, this synchronized action can be used to start the infeed movement if this has been stopped by a previous synchronized action which is still active.

Programming
WHENEVER $AA_IM[oscillation axis] == $SA_OSCILL_REVERSE_POS2[oscillation axis]
DO $AA_OVR[oscillation axis] = 0   $AA_OVR[infeed axis] = 100

Explanation of system variables:
$AA_IM[oscillation axis] Current position of oscillation axis
$SA_OSCILL_REVERSE_POS2[oscillation axis] Reversal point 2 of oscillation axis
$AA_OVR[oscillation axis] Axial override of oscillation axis
$AA_OVR[infeed axis] Axial override of infeed axis
2.2.5 Oscillation movement restarting

**Function**
The oscillation axis is started via the override whenever the distance-to-go for the currently traversed path section of the infeed axis = 0, i.e. part infeed has been executed.

**Application**
The purpose of this synchronized action is to continue the movement of the oscillation axis on completion of the part infeed movement. If the oscillation axis need not wait for completion of partial infeed, then the motion-synchronous action with which the oscillation axis is stopped at the reversal point must be omitted.

**Programming**

```plaintext
WHENEVER $AA_DTEPW[infeed axis] == 0 DO
$AA_OVR[oscillation axis] =100
```

Explanation of system variables:

- `$AA_DTEPW[infeed axis]` Axial distance-to-go for infeed axis in workpiece coordinate system
- `$AA_OVR[oscillation axis]` Axial override for oscillation axis

**Explanation of keywords:**

WHENEVER ... DO ... Whenever condition is fulfilled, then ....

2.2.6 Preventing premature starting of partial infeed

**Function**
The functions described above prevent any infeed movement outside the reversal point or the reversal point range. On completion of an infeed movement, however, restart of the next partial infeed must be prevented.

**Application**
A channel-specific flag is used for this purpose. This flag is set at the end of the partial infeed (partial distance-to-go == 0) and is deleted when the axis leaves the reversal point range. The next infeed movement is then prevented by a synchronized action.

**Programming**

```plaintext
WHENEVER $AA_DTEPW[infeed axis] == 0 DO
$AC_MARKER[index]=1
```

and, for example, for reversal point 1:

```plaintext
WHENEVER $AA_IM[Z]< $SA_OSCILL_REVERSE_POS1[Z] DO
$AC_MARKER[index]=0
```

```plaintext
WHENEVER $AC_MARKER[index]==1 DO $AA_OVR[infeed axis]=0
```
2.2 Oscillation controlled by synchronized actions

Explanation of system variables:
- $AA_DTEPW[infeed axis]$: Axial distance-to-go for infeed axis in workpiece coordinate system
- $AC_MARKER[index]$: Channel-specific flag with index
- $AA_IM[oscillation axis]$: Current position of oscillation axis
- $SA_OSCILL_REVERSE_POS1[oscillation axis]$: Reversal point 1 of oscillation axis
- $AA_OVR[infeed axis]$: Axial override for infeed axis

Explanation of keywords:
- WHENEVER ... DO ...: Whenever condition is fulfilled, then ....

2.2.7 Assignment of oscillation and infeed axes OSCILL

**Function**

One or several infeed axes are assigned to the oscillation axis with command OSCILL. The oscillation movement is started. The PLC is informed of which axes have been assigned via the VDI interface. If the PLC is controlling the oscillation axis, it must now also monitor the infeed axes and use the signals for the infeed axes to generated the reactions on the oscillation axis via 2 stop bits of the interface.

**Application**

The axes whose response has already been defined by synchronous conditions are assigned to one another for activation of oscillation mode. The oscillation movement is started.

**Programming**

OSCILL[oscillation axis] = (infeed axis1, infeed axis2, infeed axis3)

Infeed axis2 and infeed axis3 in brackets plus their delimiters can be omitted if they are not required.
2.2.8 Definition of infeeds POSP

**Function**
The control receives the following data for the infeed axis:
- Total infeed
- Part infeed at reversal point/reversal point range
- Part infeed response at end

**Application**
This instruction must be given after activation of oscillation with OSCILL to inform the control of the required infeed values at the reversal points/reversal point ranges.

**Programming**

<table>
<thead>
<tr>
<th>Function</th>
<th>End position</th>
<th>Part section</th>
<th>Mode</th>
</tr>
</thead>
</table>
| POSP[infeed axis] = (end position, part section, mode) | End position for infeed axis after all partial infeeds have been executed. | Part infeed at reversal point/reversal point range | 0

For the last two part steps, the remaining path up to the target point is divided into two equally large residual steps (default setting).

<table>
<thead>
<tr>
<th>Mode</th>
<th>1</th>
</tr>
</thead>
</table>

The part length is adjusted such that the total of all calculated part lengths corresponds exactly to the path up to the target point.
2.2 Oscillation controlled by synchronized actions

Notes
Supplementary Conditions

Availability of “Oscillation” function

Oscillation is an option with order number 6FC5 251-0AB04-0AA0.
Asynchronous and modal oscillation is available as from SW2 for NCU570, 571, 572, 573.
Oscillation with motion-synchronous actions is available with NCU 572 and 573.

Data Descriptions (MD, SD)

4.1 Machine data

### OSCILL_VELO[axis]

**SD number**: 43740

**Default value**: 0

**Min. input limit**: ***

**Max. input limit**: ***

**Significance**: Feed velocity of oscillation axis

**Application**: NC language: \( \text{PA} [\text{axis}] = \text{F} \text{value} \)

**Related to**: MD 10710 $MN_PROG_SD_RESET_SAVE_TAB

**Data type**: DOUBLE

### OSCILL_NUM_SPARK_CYCLES[axis]

**SD number**: 43750

**Default value**: 0

**Min. input limit**: 0

**Max. input limit**: ***

**Significance**: Number of sparking-out strokes which are executed on completion of oscillation movement.

**Application**: NC language: \( \text{OSNSC} [\text{axis}] = \text{number of strokes} \)

**Related to**: MD 10710 $MN_PROG_SD_RESET_SAVE_TAB

**Data type**: DWORD

### OSCILL_END_POS[axis]

**SD number**: 43760

**Default value**: 0

**Min. input limit**: ***

**Max. input limit**: ***

**Significance**: Position to be approached by oscillation axis after execution of sparking-out strokes.

**Application**: NC language: \( \text{OSE} [\text{axis}] = \text{position} \)

**Related to**: MD 10710 $MN_PROG_SD_RESET_SAVE_TAB

**Data type**: DOUBLE

### OSCILL_CTRL_MASK[axis]

**SD number**: 43770

**Default value**: 0

**Min. input limit**: –

**Max. input limit**: –

**Significance**: Bit screen form, see following table 4-1

**Application**: NC language: \( \text{OSCTRL} [\text{axis}] = \text{(setting options, resetting options)} \)

**Related to**: MD 10710 $MN_PROG_SD_RESET_SAVE_TAB

**Data type**: BYTE

Examples

Preconditions
The examples given below require components of the NC language specified in the sections entitled

- Asynchronous oscillation

and

- Oscillation controlled by synchronized actions.

6.1 Example of asynchronous oscillation

Task
The oscillation axis Z must oscillate between −10 and 10. Approach reversal point 1 with exact stop coarse and reversal point 2 without exact stop. The oscillation axis feedrate must be 5000. 3 sparking-out strokes must be executed at the end of the machining operation followed by approach by oscillation axis to end position 30. The feedrate for the infeed axis is 1000, end of the infeed in X direction is at 15.

Program section
OSP1[Z]=−10 ; Reversal point 1
OSP2[Z]=10 ; Reversal point 2
OST1[Z]=−1 ; Stop time at reversal point 1: Exact stop coarse
OST2[Z]=−2 ; Stop time at reversal point 2: Without exact stop
FA[Z]=5000 ; Feedrate for oscillation axis
OSNSC[Z]=3 ; Three sparking-out strokes
OSE[Z]=30 ; End position
OS[Z]=1 F500 X15 ; Start oscillation, infeed X axis
; with feedrate 5000, infeed target 15
6.1 Example of asynchronous oscillation

Fig. 6-1 Sequences of oscillation movements and infeed, example 1
6.2 Example 1 of oscillation with synchronized actions

Task
Direct infeed must take place at reversal point 1; the oscillation axis must wait until the part infeed has been executed before it can continue traversal. At reversal point 2, the infeed must take place at a distance of -6 from reversal point 2; the oscillation axis must not wait at this reversal point until part infeed has been executed. Axis Z is the oscillation axis and axis X the infeed axis. (see 2.2).

Note
The setting data OSCILL_REVERSE_POS_1/2 are values in the machine coordinate system; therefore comparison is only suitable with $AA_IM[n]$

Program section
; Example 1: Oscillation with synchronized actions
OSP1[Z]=10 OSP2[Z]=60 ; Define reversal points 1 and 2
OST1[Z]=−2 OST2[Z]=0 ; Reversal point 1: Without exact stop
FA[Z]=5000 FA[X]=250 ; Feedrate for oscillation axis, feedrate for infeed axis
OSCTRL[Z]=(1+8+16,0) ; Deactivate oscillation movem. at reversal point 1
; Sparking-out after deletion of distance-to-go
; and approach end position
; Approach programmed reversal
; point after deletion of distance-to-go
OSNSC[Z]=3 ; 3 sparking-out strokes

; and set axial override of oscillation axis to 100\% ("start" oscillation).
WHENEVER $AC_MARKER[1]==1 DO $AA_OVR[X]=0 $AA_OVR[Z]=100

; If the current position of the oscillation axis in the machine coordinate system
; is equal to reversal position 1,
; then set the axial override of the oscillation axis to 100\% and set the axial override of the infeed axis to 0\% (in order
; to cancel the second synchronized action once).

OSCILL[Z]=(X) POSP[X]=(5,1,1) ; Assign axis X as infeed axis
to oscillation axis Z; axis X must
infeed to end position 5 in part steps of
1 and the total of all part lengths
must correspond exactly to the end position

M30 ; Program end

Fig. 6-2 Sequences of oscillation movements and infeed, example 1
6.3 Example 2 of oscillation with synchronized actions

Task

No infeed must take place at reversal point 1. At reversal point 2, the infeed must take place at distance \( ii2 \) from reversal point 2; the oscillation axis must wait at this reversal point until part infeed has been executed. Axis Z is the oscillation axis and axis X the infeed axis.

With $\text{A}_{\text{IM}}[S1]$, actual values for spindles can be evaluated. For spindles and rotary axis modulo calculation applies depending on the machine data $\text{MA}_{\text{ROT IS MODULO}}$ and $\text{MA}_{\text{DISPLAY IS MODULO}}$ modulo calculation.
7.5 Main run variables for motion-synchronous actions

| $ISAC\_DTEPW$ | Remaining path for infeed, oscillation in PCS (not P2) (distance to end, pendulum, baseCoor) (Real) |
| $ISAC\_PATHN$ | (distance to end, pendulum, workpieceCoor) (Real) (path parameter normalized) (Real) Normalized path parameter: 0 for block start, up to 1 for block end |
| $ISAA\_LOAD[<axial expression>]$ | Drive load (for 611D only) |
| $ISAA\_POWER[<axial expression>]$ | Real drive output in W (for 611D only) |
| $ISAA\_TORQUE[<axial expression>]$ | Drive torque setpoint in Nm (for 611D only) |
| $ISAA\_CURR[<axial expression>]$ | Current value of axis (for 611D only) |
| $ISAC\_MARKER[<arithmetic expression>]$ | Marker variable: can be used in synchronized actions for creating complex conditions. There are 8 markers (index 0–7). With reset, the markers are set to 0. Ex.: WHEN .....DO $ISAC\_MARKER[0]=2$ WHEN .....DO $ISAC\_MARKER[0]=3$ WHEN $ISAC\_MARKER[0]==3$ DO $ISAC\_OVR=50$ It is possible to read or overwrite the markers independently of synchronized actions in the part program: IF $ISAC\_MARKER == 4$ GOTOF SPRUNG |
| $ISAC\_PARAM[<arithmetic expression>]$ | Floating point parameter for synchronized actions. Serves for buffering and evaluation of synchronized actions. There are 50 parameters (index 0–49) available. |
| $ISAA\_OSCILL\_REVERSE\_POS1[<axial expression>]$ | Current reverse positions 1 and 2 for oscillation: In each case, the current setting data value is read from $SA\_OSCILL\_REVERSE\_POS1$ or $SA\_OSCILL\_REVERSE\_POS2$. Changes to the reversal positions in the setting data thus become effective when oscillation is active, i.e. during an active synchronized action. |

**Conditions**

Conditions for motion-synchronous actions are formulated:

Brief Description

Rotary axes are used on many modern machine tools. They are required for tool and workpiece orientation, auxiliary movements and various other technological or kinematic purposes.

A typical example of a machine tool requiring the use of rotary axes is the 5-axis milling machine. Only with the aid of rotary axes can the tip of the tool be positioned on any point of the workpiece on this type of machine.

Depending on the type of machine, many different demands are placed on a rotary axis. In order that the control can be adapted to the various types of machine, the individual rotary axis functions can be activated by means of machine data or special programming.

Rotary axes are always programmed in degrees. They are generally characterized by the fact that they assume the same position again after exactly one rotation (modulo 360°). Depending on the application in question, the traversing range of the rotary axis can be limited to less than 360° (e.g. on swivel axes for tool holders) or may be endless (e.g. when tool or workpiece is rotated).

The behavior and features of rotary axes are, in many aspects, identical to those of linear axes. The following functional description is limited to a description of the special features of rotary axes and the differences compared with linear axes.
1 Brief description

**Detailed Description**

2.1 General

**Definition of rotary axis**
An axis can be declared as a rotary axis by means of machine data IS_ROT_AX. If the axis is already defined as a geometry axis, alarm 4200 is output. Only when an axis has been declared as a rotary axis can it perform or use the functions described on the following pages (e.g. unlimited traversing range, modulo display of axis position, etc.). Several axes can be simultaneously declared as rotary axes.

**Types of rotary axis**
Depending on the particular application, the operating range of a rotary axis can be endless (i.e. endlessly turning in both directions MD: ROT_IS_MODULO = 1) or limited by software limit switches (e.g. operating range between 0 ... 60°) or restricted to a specific number of rotations (e.g. 1000°).

The following list presents some typical applications of rotary axes:

**Typical applications**

- 5-axis machining (operating range limited or unlimited)
- Rotary axis for eccentric machining (unlimited operating range)
- Rotary axis for cylindrical or contour grinding (unlimited operating range)
- C axis with TRANSMIT (unlimited operating range)
- Rotary axis on winding machines (unlimited operating range)
- Rotary workpiece axis (C) on hobbing machines (unlimited operating range)
- Round tool magazines and tool turrets (unlimited operating range)
- Rotary axis for peripheral surface transformation (limited operating range)
- Swivel axes for gripping (operating range 360°)
- Rotary axes for swivelling (operating range < 360°; e.g. 60°)
- Milling swivel axis (A) on hobbing machines (operating range e.g. 90°)
Axis addresses

Coordinate axes and directions of movement of numerically controlled machine tools are designated according to DIN. DIN 66025 specifies the following axis addresses for rotary or swivel axes: A, B and C with X, Y and Z as middle axis; i.e. A rotates around X, B rotates around Y and C rotates around Z (see diagram below). The positive direction of a rotary axis corresponds to a movement to the right looking in the positive axis direction of the corresponding middle axis.

Extended addressing (e.g. C2=) or freely configured axis addresses can be used for additional rotary axes.

**Note**

If the X1, Y1 or Z1 axis is declared to be a rotary axis, then the operating modes cannot be selected or changed. MD 20050: AXCONF_GEOAX_ASSIGN_TAB (assignment of geometry axis to channel axis) must be adapted to suit the corresponding axis.
The following units of measurement apply as standard to data inputs and outputs for rotary axes:

<table>
<thead>
<tr>
<th>Physical quantity</th>
<th>Unit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Angular position</td>
<td>degrees</td>
</tr>
<tr>
<td>Programmed angular speed</td>
<td>Degrees/minute</td>
</tr>
<tr>
<td>MD for angular speed</td>
<td>Rev/min 1)</td>
</tr>
<tr>
<td>MD for angular acceleration</td>
<td>Rev/sec² 1)</td>
</tr>
<tr>
<td>MD for angular smoothing</td>
<td>Rev/sec³ 1)</td>
</tr>
</tbody>
</table>

1) These units are interpreted by the control with the axis-specific machine data as soon as the axis is declared as a rotary axis. The user has the option of defining other units for data input/output using machine data.

References: /FB/, G2, “Velocities, Setpoint/Actual-Value Systems, Closed-Loop Control”

The axis operating range can be defined by means of axis-specific machine and setting data (software limit switches and working area limitations). As soon as the modulo conversion is activated for the rotary axis (MD: ROT_IS_MODULO = “1”), the operating range is unlimited and the software limit switches and working area limitations are inactive.

The value range for the position display can be set to the modulo 360° representation that is frequently selected for rotary axes (MD: DISPLAY_IS_MODULO = “1”).

The programmed feedrate \( F \) corresponds to an angular speed [degrees/min] in the case of rotary axes.

If rotary axes and linear axes traverse along a common path with G94 or G95, the feed should be interpreted in the unit of measurement of the linear axes [e.g. mm/min, inch/min].

The tangential speed of the rotary axis refers to the diameter \( D_E \) (unit diameter \( D_E=360/\pi \)). In the case of unit diameter \( D=D_E \), the programmed angular speed in degrees/min and the tangential velocity in mm/min (or inch/min) are numerically identical.

The following applies generally for the tangential speed:

\[
F = \frac{F_W \cdot D}{D_E} \quad F = \text{Tangential speed [mm/min]}
\]

\[
F_W = \text{Angular speed [degrees/min]}
\]

\[
D = \text{Diameter at which \( F \) effective [mm]}
\]

where \( D_E = 360 / \pi \)

\[
D_E = \text{Unit diameter [mm]}
\]

\[
\pi = \text{Circle constant Pi}
\]
In JOG mode the behavior of the axis/spindle also depends on the setting of setting data JOG_REV_IS_ACTIVE (revolutional feedrate when JOG active).

- If this setting data is active, an axis/spindle is always moved with revolutional feedrate MD JOG_REV_VEL (revolutional feedrate with JOG) or MD JOG_REV_VEL_RAPID (revolutional feedrate with JOG with rapid traverse overlay) depending on the master spindle.

- If the setting data is not active, the behavior of the axis/spindle depends on the setting data ASSIGN_FEED_PER_REV_SOURCE (revolutional feedrate for positioning axes/spindles).

- If the setting data is not active, the behavior of a geometry axis on which a frame with rotation is effective depends on the channel-specific setting data JOG_FEED_PER_REV_SOURCE (In JOG mode, revolutional feedrate for geometry axes on which a frame with rotation is effective).
2.2 Modulo 360°

Term Modulo 360°

Rotary axes are frequently programmed in the 360° representation mode. The axis must be defined as a rotary axis in order to use the modulo feature.

With respect to a rotary axis, the term “Modulo” refers to imaging of the axis position internally in the control within the range from 0° to 359.999°. With path settings > 360° (e.g. for incremental dimension programming using G91), the axis position is imaged in the value range between 0° to 360° through a conversion process in the control. The imaging process is applied in JOG and AUTOMATIC mode. The service display is an exception.

In the diagram below, the absolute position of the rotary axis in the positive direction of rotation is represented as a spiral. An arrow marks the actual absolute position (Example: Point C' = 420°). By sliding the arrow back around the circle (position 0° of the spiral and circle are identical), it is possible to determine a modulo position within the 360° range corresponding to every absolute position. In the example below, absolute position point C' = 420° is mapped onto point C = 60° through the modulo conversion process.

Fig. 2-2 Modulo 360° imaging

Machine data settings

Using machine data it is possible to define the programming and positioning settings (MD: ROT_IS_MODULO) and the position display (MD DISPLAY_IS_MODULO) in modulo 360° for each individual rotary axis to suit the requirements of individual machine tools.
2.2 Modulo 3605

Axis is modulo

MD: ROT_IS_MODULO = "1":

Activation of this machine data allows the special rotary axis action implemented in the system to be utilized (see Section 2.3.1), defining the positioning action of the rotary axis for programming (G90, AC, ACP, ACN or DC). A modulo 360° imaging process is executed internally in the control after the current zero offsets have been taken into account. The calculated destination position is subsequently approached within a single revolution. The software limit switches and the working area limitations are ineffective and the operating range is unlimited (endlessly turning rotary axis). Please see Section 2.3 on the programming of rotary axes or MD: ROT_IS_MODULO for further information.

Modulo position display

MD: DISPLAY_IS_MODULO = 1:

A "modulo 360°" (1 rotation) position display is frequently required for rotary axes, i.e. when the axis is rotating in the positive direction, the display is periodically reset from 359.999° to 0.000° in the control system; with a negative direction of rotation, the axis positions are also displayed in the 0°...359.999° range.

MD: DISPLAY_IS_MODULO = 0:

In contrast to the modulo 360° display method, absolute positions are indicated by the absolute position display, e.g. +360°, after 1 rotation and +720° after 2 rotations, etc. In this case, the display range is limited by the control in accordance with the linear axes.

Note

The modulo 360° display method should always be selected for a modulo axis (ROT_IS_MODULO = "1").
2.3 Programming of rotary axes

Note
For general information on programming, please refer to:
References: /PAG/Programming Guide Fundamentals

General
The machine data ROT_IS_MODULO (modulo conversion for rotary axis) defines whether the rotary axis behaves in the same way as a linear axis during programming and positioning or whether the special features of the rotary axis are incorporated. These features and the differences (mainly with respect to absolute dimension programming) are explained on the following pages.

2.3.1 Rotary axis with active modulo conversion (endlessly turning rotary axis)

Activate modulo conversion
⇒ MD: ROT_IS_MODULO = “1”
Recommendation: it is also advisable to set the position display to modulo 3605 (MD: DISPLAY_IS_MODULO = “1”).

Absolute dimension programming (AC, ACP, ACN, G90)
Example of positioning axis: POS[axis name] = ACP(value)
- The value identifies the target position of the rotary axis within the 0 ... 359.999° range. In the case of values with a negative sign or ≥ 360° alarm 16830 “Incorrect modulo position programmed” is output.
- ACP (positive) and ACN (negative) define the traversing direction of the rotary axis unambiguously (irrespective of actual position).
- When programming exclusively with AC or with G90, the traversing direction depends on the actual position of the rotary axis. If the destination position is larger than the actual position, the axis traverses in the positive direction, otherwise it traverses in the negative direction.
- Use of ACP and ACN: with asymmetrical workpieces, it must be possible to define the traversing direction to prevent collisions during rotation.
Example:
(see diagram below): Start position of C is 0°

<td>C traverses in the negative rotational direction to position 300°</td>
</tr>
<tr>
<td>POS[C] = ACP(240)</td>
<td>C traverses in the positive rotational direction to position 240°</td>
</tr>
<tr>
<td>POS[C] = AC (0)</td>
<td>C traverses in the negative rotational direction to position at 0°</td>
</tr>
</tbody>
</table>

**POS[axis name] = DC(value)**

- The value identifies the destination position of the rotary axis in a range from 0 to 359.999°. For values with a negative sign or ≥ 360° alarm 16830 “incorrect modulo position programmed” is output.
- With DC (Direct Control), the rotary axis approaches the programmed absolute position via the **shortest route** within one revolution (traversing movement max. ±180°).
- The control calculates the direction of rotation and the traversing distance according to the actual position. If the distance to be traversed is the same in both directions (180°), the positive direction receives preference.
Example application of DC: the rotary table is required to approach the changeover position in the shortest time (and therefore across the shortest path).

If DC is programmed with a linear axis, alarm 16800 “DC traversing instruction cannot be used”.

**Example:**
(see diagram below): Start position of C is 0°

<table>
<thead>
<tr>
<th>Programming</th>

</tr>
<tr>
<td>POS[C] = DC (60)</td>
<td>C axis traverses along the shortest path to position 60°. Since the distance in this case is equal to 180° in both directions, the positive direction has preference.</td>
</tr>
</tbody>
</table>

![Diagram showing examples of DC programming](image)

**Incremental dimension programming (IC, G91)**

Example of positioning axis: **POS[axis name] = IC(+/-value)**

- The value identifies the traversing distance of the rotary axis. The value can be negative or \( \pm 360° \).
- The sign of the value mandatorily specifies the traversing direction of the rotary axis.
- Example application: milling a spiral groove across several revolutions
2.3 Programming of rotary axes

Example:

\[
\text{POS}[C] = \text{IC}(720) \quad \text{C axis traverses incrementally through} \\
\text{720° (2 revolutions) in the positive direction}
\]

\[
\text{POS}[C] = \text{IC}(-180) \quad \text{C axis traverses incrementally through} \\
\text{180° in the negative direction}
\]

Endless traversing range

As soon as the modulo function is active, no limit is placed on the traversing range (software limit switches are not active). The rotary axis can now be programmed to traverse continuously.

Example:

\[
\text{LOOP:} \\
\text{POS}[C] = \text{IC}(720) \\
\text{GOTO} \text{B LOOP}
\]

2.3.2 Rotary axis without modulo conversion

Deactivate modulo conversion

\[
\Rightarrow \text{MD:ROT_IS_MODULO = “0”}
\]

Absolute dimension programming (AC, G90)

Example of positioning axis: \[
\text{POS[axis name] = AC (+/−value)}
\]

- The value and its leading sign provide a unique identification of the destination position of the rotary axis. The value can also be \(±360°\). The position value is limited by the software limit switch positions.
- The traversing direction is ascertained by the control according to the leading sign of the actual position of the rotary axis.
- If ACP or ACN are programmed, alarm 16810 “ACP traversing instruction cannot be used” or alarm 16820 “ACN traversing instruction cannot be used” is output.
- Example application: linear movements are incorporated in the rotary axis (cam gear); certain end positions may therefore not be overtraveled.

Example:

<table>
<thead>
<tr>
<th>Programming</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>\text{POS}[C] = AC (-100)</td>
<td>\text{Rotary axis C approaches position }-100°; \text{the traversing direction depends on the starting position}</td>
</tr>
<tr>
<td>\text{POS}[C] = AC (1500)</td>
<td>\text{Rotary axis C traverses to the position at 1500°}</td>
</tr>
</tbody>
</table>
Absolute dimension programming across the shortest path (DC)

POS[axis name] = DC(value)

Even if the rotary axis is not defined as a modulo axis, the axis can still be positioned with DC (direct control). The response is the same as on a modulo axis.

- The value identifies the destination position of the rotary axis in a range from 0 to 359.999° (modulo 360°). In the case of values with a negative sign or of ≥ 360°, alarm 16830 “Incorrect modulo position programmed” is output.

- With DC (Direct Control), the rotary axis approaches the programmed absolute position via the shortest route within one revolution (traversing movement max. ±180°).

- The control calculates the direction of rotation and the traversing distance according to the actual position (in relation to modulo 360°). If the distance to be traversed is the same in both directions (180°), the positive direction receives preference.

- Example application of DC: the rotary table is required to approach the changeover position in the shortest time (and therefore across the shortest path).

- If DC is programmed with a linear axis, alarm 16800 “DC traversing instruction cannot be used”.

Example:

<table>
<thead>
<tr>
<th>Programming</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>POS[C] = AC (7200)</td>
<td>Rotary axis C traverses to position 7200°;</td>
</tr>
<tr>
<td></td>
<td>the traversing direction depends on the starting position</td>
</tr>
<tr>
<td>POS[C] = DC (300)</td>
<td>Rotary axis C traverses along the shortest path to the “modulo” position at 300°.</td>
</tr>
<tr>
<td></td>
<td>C therefore traverses through 60° in the negative direction of rotation and stops</td>
</tr>
<tr>
<td></td>
<td>at the absolute position at 7140°.</td>
</tr>
<tr>
<td>POS[C] = AC (7000)</td>
<td>Rotary axis C traverses to the absolute position at 7000°;</td>
</tr>
<tr>
<td></td>
<td>here, C traverses through 140° in the negative direction of rotation</td>
</tr>
</tbody>
</table>

Note: In this example, it is advisable to activate the modulo 360° display (MD: DISPLAY_IS_MODULO = “1”).

Incremental dimension programming (IC, G91)

Example of positioning axis: POS[axis name] = IC(+/−value)

When programming with incremental dimension, the rotary traverses across the same path as with the modulo axis. In this case, however, the traversing range is limited by the software limit switches.

- The value identifies the traversing distance of the rotary axis. The value can be negative or ≥ +/-360°.

- The leading sign of the value defines the traversing direction. Please see section 2.3.2 for an example.

Limited traversing range

The traversing range is limited as with linear axes. The range limits are defined by the plus and minus software limit switches.
2.3.3 Miscellaneous programming features relating to rotary axes

**Offsets**
TRANS (absolute) and ATRANS (additive) can be applied to rotary axes.

**Scales**
SCALE or ASCALE are not suitable for rotary axes since the control system always bases its modulo calculation on a 360° full circle.

**Set actual value**
PRESETON is possible.

**Indexing axes**
References: /FB/, T1, “Indexing Axes”
2.4 Start-up of rotary axes

Procedure

The procedure for starting up rotary axes is identical to that for linear axes with a small number of exceptions. It should be noted that the units of the axis-specific machine and setting data on the control are interpreted as follows as soon as the axis has been defined as a rotary axis (MD: IS_ROT_AX = 1):

- Position: in “degrees”
- Speed: in “rev/minute”
- Acceleration: in “rev/second²”
- Smoothing: in “rev/second³”

Special MDs

The special machine data of the rotary axis described in Section 4 must also be entered depending on the application.

- MD: ROT_IS_MODULO: Modulo conversion for positioning and programming
- MD: DISPLAY_IS_MODULO: Modulo conversion for position display
- MD: INT_INCR_PER_DEG: Precision of angular position calculation

The following overview lists the possible combinations of these machine data for a rotary axis.

Table 2-2 Possibilities for combining machine data of rotary axes

</tbody>
</table>

### JOG velocity for rotary axes

A jog velocity that is valid for all rotary axes can be set with SD: JOG_ROT_AX_SET_Velo (JOG velocity for rotary axes).

If a value of “0” is entered in the setting data, then the axis MD: JOG_VELO (conventional axis velocity) acts as the JOG velocity for the rotary axis.

**References:** /FB/, H1, “Manual and Handwheel Travel”
# 2.5 Special features of rotary axes

## Software limit switches
The software limit switches and working area limitations are operative and are required for swivel axes with a restricted operating range. For endlessly turning rotary axes with (MD: ROT_IS_MODULO=1), however, the software limit switches and working area limitations are set inactive.

**References:** /FB/, A3, “Axis Monitoring”

## Mirroring of rotary axes
Mirroring can be implemented for rotary axes with programming commands MIRROR(C) and AMIRROR(C).

**References:** /FB/, R1, “Reference Point Approach”

## Reference point approach

## Spindles as rotary axes
For notes concerning the use of spindles and rotary axes (C axis operation), please refer to:

**References:** /FB/, S1, “Spindles”

Supplementary Conditions

There are no supplementary conditions stipulated for this Description of Functions.

Data Descriptions (MD, SD)

4.1 Axis/spindle-specific machine data

<table>
<thead>
<tr>
<th>30320</th>
<th>DISPLAY_IS_MODULO</th>
</tr>
</thead>
<tbody>
<tr>
<td>MD number</td>
<td>Position display is modulo 360°</td>
</tr>
</tbody>
</table>

Default value: 1
Min. input limit: 0
Max. input limit: 1
Changes effective after Power On
Protection level: 2
Unit: --
Data type: BOOLEAN
Applies from SW version: 1.1

Significance:

1: "Modulo 360°" position display is active:
The position display of the rotary axis or spindle (for basic or machine coordinate system) is defined as "Modulo 360°". The control resets the position display internally to 0.000 degrees following each cycle of 359.999 degrees. The display range is always positive and always between 0° and 359.999°.

0: Absolute position display is active:
In contrast to the modulo 360° display method, absolute positions are indicated by the absolute position display, e.g. +360° after 1 rotation and +720° after 2 rotations, etc.
In this case, the display range is limited by the control in accordance with the linear axes.

MD irrelevant for...... Linear axes MD: IS_ROT_AX = 0

Application

• With continuously rotating axes (MD: ROT_IS_MODULO = "1") it is advisable to activate the position display with modulo 360°.
• The position display for spindles must always be activated with modulo 360°.

Related to .... MD: IS_ROT_AX = 1 "axis is rotary axis"
### 4.1 Axis/spindle-specific machine data

#### 34220

<table>
<thead>
<tr>
<th>MD number</th>
<th>ENC_ABS_TURNS_MODULO[n]</th>
</tr>
</thead>
<tbody>
<tr>
<td>MD number</td>
<td>Absolute encoder range for rotary encoders: 0 ... max. no. encoders – 1</td>
</tr>
<tr>
<td>Default value: 4096, 4096</td>
<td>Min. input limit: 1</td>
</tr>
<tr>
<td>Changes effective after Power On</td>
<td>Protection level: 2 / 7</td>
</tr>
<tr>
<td>Data type: DWORD</td>
<td>Applies from SW version: 2.2</td>
</tr>
</tbody>
</table>

**Significance:**
The absolute position of a rotary axis is reduced to the following range after switching on an absolute encoder:
That is, if a MODULO conversion is performed, the actual position read is greater than the position allowed by the MD ENC_ABS_TURNS_MOTOR.

0 degrees <= position <= n*360 degrees, (with n = ENC_ABS_TURNS_MODULO)

**Note:** In SW 2.2, the position is reduced to this range when the control system/encoder is switched on. With SW 3.6 and higher, half this value represents the maximum permissible traversing path when the control or encoder is switched off.

**Special cases, errors, .....**

The MD is only relevant for rotary encoders (with linear and rotary axes).

**Important recommendation:**
The default value "1 encoder revolution" was changed to "4096" from software version 3.6.
The new value provides a more robust setting for the most commonly used encoder types.
When using an encoder with smaller multi-turn information, or when using single-turn encoders, the value must be decreased accordingly. In any case, for multi-turn absolute encoders the value should be changed to the maximum quantity supported by the encoder so that the unambiguous traversing range that is increased as a result can be utilized (Note: This value also influences the permissible position offset when the encoder or power supply is switched off).

**Related to ....**
Drive MD 1021, ENC_ABS_TURNS_MOTOR,
Drive MD 1031, ENC_ABS_TURNS_DIRECT

#### 30300

<table>
<thead>
<tr>
<th>MD number</th>
<th>IS_ROT_AX</th>
</tr>
</thead>
<tbody>
<tr>
<td>MD number</td>

<tr>
<td>Changes effective after Power On</td>
<td>Protection level: 2</td>
</tr>
<tr>
<td>Data type: BOOLEAN</td>
<td>Applies from SW version: 1.1</td>
</tr>
</tbody>
</table>

**Significance:**
1: Axis: The axis is defined as a "rotary axis"
   - The special functions of the rotary axis are active or can be activated by means of additional machine data according to the type of machine required (see below).
   - The unit of measurement is degrees.
   - The units of the axis-specific machine and setting data are interpreted as follows with the standard control setting:
     - Position in "degrees"
     - Speed in "rev/minute"
     - Acceleration in "rev/second²"
     - Smoothing in "rev/second³"
   - Spindle:
     The machine data should always be set to "1" for a spindle, otherwise alarm 4210 "rotary axis declaration missing" is output.
   0: The axis is defined as a "linear axis".

**Special cases, errors, .....**
for axis: alarm 4200 if the axis is already defined as a geometry axis.
for spindle: alarm 4210

**Related to ....**
The following machine data are effective only after activation of MD:IS_ROT_AX = "1":
   - MD: ROT_IS_MODULO "Modulo conversion for rotary axis"
   - MD: DISPLAY_IS_MODULO "Position display is modulo"
   - MD: INT_INCR_PER_DEG "Calculation precision for angle positions"

Notes
Signal Descriptions

No separate signals exist for this Description of Functions.

Example

Rotary axes are frequently used on 5-axis milling machines to swivel the tool axis or rotate the workpiece. These machines can position the tip of a tool on any point of the workpiece and take up any position on the tool axis. Various milling heads are required according to the application. Fig. 6-1 illustrates a fork head and an inclined axis head as example arrangements for rotary axes.

Brief Description

Synchronous Spindle

This function (see Chapter 3) enables synchronization between a leading and following spindle with high angle accuracy.

It also offers the option of on-the-fly transfer of the workpiece from spindle 1 to spindle 2 during operation on turning machines for the purpose, for example, of final machining. Advantage: Avoidance of downtimes.

Apart from synchronizing the spindle speed, it is also possible to specify the relative angular position of the spindles in relation to one another, e.g. for on-the-fly, position-oriented transfer of workpieces.

On-the-fly transfer of workpieces between leading spindle (LS) and following spindle (FS):

- $n_{FS} = n_{LS}$  
  Speed synchronism

- $\psi_{FS} = \psi_{LS}$  
  Position synchronism

or

- $\psi_{FS} = \psi_{LS} + \Delta\psi$  
  Position synchronism with angular offset

Polygonal Machining

As an additional feature, specification of an integer, multiple speed ratio $k_\psi$ between the main spindle and a "tool spindle" provides the basis for polygonal machining (polygonal turning).

Polygonal turning:

- $n_{FS} = k_\psi \cdot n_{LS}$

Synchronous operation is selected and deselected via the CNC part program.

The synchronous spindle pairs for each machine can be assigned a fixed configuration by means of channel-specific machine data or defined for specific applications via the CNC part program.

Up to 2 synchronous spindle pairs can be operated in each NC channel.

SW 5 and higher

Any number of following spindles in any channels on an NCU can be coupled to one leading spindle. The only possible restriction could be imposed by the real CPU time requirement.
1 Brief description

Fig. 1-1  Synchronous mode, on-the-fly workpiece transfer from spindle 1 to spindle 2

Fig. 1-2  Polygonal turning
Detailed Description

2.1 General functionality

2.1.1 Synchronous mode

Explanations

| <Axial expression>: can be: | – Axis identifier |
| – Spindle identifier |
| <Axis identifier>: C (if spindle 1 has the identifier C in axis mode) |
| <Spindle identifier>: Sn, SPI(n) with n = Spindle number 1, 2, ... |
| <Spindle number>: according to the spindle number defined in MD 35000:SPIND_ASSIGN_TO_MACHAX |

Synchronous spindle pair

Synchronous operation involves a following spindle (FS) and a leading spindle (LS), referred to as the synchronous spindle pair. The following spindle imitates the movements of the leading spindle when a coupling is active (synchronous operation) in accordance with the defined functional interrelationship.

Synchronous mode

Synchronous mode (also referred to as “Synchronous spindle operation”) is another spindle operating mode. Before synchronous mode is activated, the following (slave) spindle must have been switched to position control. Synchronous operation is activated for the following spindle when the coupling is activated. As soon as the coupling is deactivated, the following spindle switches back to open-loop control mode.

As soon as synchronous operation has been activated for the following spindle, IS “Synchronous operation” (DB31, ... DBX84.4) = 1 is transmitted to the PLC.

Number of synchronous spindles (SW 4 and earlier)

Two synchronous spindle couplings can be operated simultaneously in each NC channel.

Number of synchronous spindles (SW 5 and higher)

Any number of following spindles in any channels on an NCU can be coupled to one leading spindle.

Configured or user-defined coupling

Synchronous spindle couplings can be defined both

- as a fixed configuration via channel-specific machine data (referred to below as “fixed coupling configuration”) and
- as a freely defined coupling via language instructions (COUP...) in the part program (referred to below as “user-defined coupling”).

The following variants are possible:

1. A fixed configuration for a coupling can be programmed via machine data. In addition, a second coupling can be freely defined via the part program.
2. No coupling is configured via machine data. In this case, two couplings can be user-defined and parameterized via the part program.

Options in synchronous mode

The following functional options are available in synchronous mode:

- Following and leading spindle rotate at the same speed
  \( n_{FS} = n_{LS} ; \text{speed ratio } k_U = 1 \)

- LS and FS rotating in the same direction or in opposite directions (can be defined by specifying positive or negative speed ratio \( k_U \))

- Following and leading spindles rotate at different speeds
  \( n_{FS} = k_U \cdot n_{LS} ; \text{speed ratio } k_U \neq 1 \)
  Application: Polygonal turning

- Adjustable angular position between FS and LS \( \theta_{FS} = \theta_{LS} + \Delta \theta \)
  The spindles rotate at synchronous speed with a defined angular offset between the LS and FS (position-synchronous coupling).
  Application: Shaped workpieces

- Activation of synchronous operation between LS and FS can take place when the spindles are in motion or at standstill.

- The full functionality of the open-loop and position control modes is available for the leading spindle.

- When synchronous mode is not active, the FS and LS can be operated in all other spindle modes.

- The speed ratio can also be altered when the spindles are in motion in active synchronous mode.

- With synchronous spindle coupling switched on, the offset of the FS to the LS (overlaid movement) can be altered.

Definition of synchronous spindle pair

The spindles to be coupled (FS, LS) must be defined before synchronous mode is activated.

This can be done in two ways depending on the application in question:

1. Fixed coupling configuration

   The machine axes which are to act as the leading and following spindles must be defined in channel-specific MD: \texttt{COUPLE\_AXIS\_1[n]}.

   The machine axes programmed as the LS and FS for this coupling configuration cannot be altered by the NC part program.

   If necessary, the coupling parameters can be modified with the NC part program.

2. User-defined coupling:

   Couplings can be created and altered in the NC part program with language instruction “\texttt{COUPDEF(FS,LS,..)}”. If a new coupling relationship is to be defined, it may be necessary to delete an existing user-defined coupling beforehand (with language instruction \texttt{COUPDEL(FS,LS)}).

   The axis identifiers (Sn, SPI(n)) for the following and leading spindles must be programmed with FS and LS for every language instruction \texttt{COUP...}, thus ensuring that the synchronous spindle coupling is unambiguously defined.
The valid spindle number must be assigned to a machine axis in the axis-specific MD: SPIND_ASSIGN_TO_MACHAX.

References: /PA/, Programming Guide

The PLC is informed of whether a machine axis is programmed as a following or leading spindle by means of interface signals “FS active” (DB31, ... DBX99.1) and “LS active” (DB31, ... DBX99.0).

### Speed ratio

The speed ratio is programmed with separate numerical values for numerator and denominator (speed ratio parameters). It is therefore possible to specify the speed ratio very exactly, even with rational numbers.

**General rule:**

$$ k_{\text{ratio}} = \frac{\text{Speed ratio parameter numerator}}{\text{Speed ratio parameter denominator}} = \frac{\dot{U}_{\text{numerator}}}{U_{\text{denominator}}} $$

The value range of the speed ratio parameter ($\dot{U}_{\text{numerator}}, U_{\text{denominator}}$) is virtually unlimited internally in the control.

The speed parameters for the coupling configured via machine data can be set in channel-specific setting data (SD: COUPLE_RATIO_1[n]). In addition, the ratio can be altered with language instruction COUPDEF(FS, LS, $\dot{U}_{\text{numerator}}, U_{\text{denominator}}$). The values entered in the setting data are not overwritten in this case (default settings).

The ratio for the coupling defined via the NC part program can only be input with language instruction COUPDEF(...).

The new ratio parameters take effect as soon as the COUPDEF instruction has been processed.

### Coupling characteristics

The following characteristics can be defined for every synchronous spindle coupling:

- **Block change response**

  The condition to be fulfilled for a block change can be defined on activation of synchronous operation or on alteration of the ratio or the speed defined angular offset when the coupling is active:
  - Block changes immediately
  - Block change in response to “Fine synchronism”
  - Block change in response to “Coarse synchronism”
  - Block change in response to IPOSTOP (i.e. after setpoint-based synchronism)
  - Check of the synchronism conditions at an arbitrary moment with WAITC.
2.1 General functionality

- **Type of coupling** between FS and LS
  
  The position setpoint or the actual position value of the leading spindle can be used as the reference value for the following spindle. The following coupling types can therefore be selected:

1. **Setpoint coupling (DV)**
   
   Application in position-controlled mode. The control dynamic response of both spindles should coincide as far as possible. The setpoint coupling should be used preferably.

2. **Actual-value coupling (AV)**
   
   Application if position control of the LS is not possible or with great deviation of the control characteristics between FS and LS. The setpoints for the FS are derived from the actual values of the LS. The synchronism is with changing LS speed of worse quality than with setpoint coupling.

3. **Speed coupling (VV)**
   
   Internally, the speed coupling is a setpoint coupling. The requirements for FS and LS are lower. Position control and measuring systems are not required for FS and LS.

   The position offset between FS and LS is undefined.

   The coupling characteristics are selected via machine data for fixed coupling configurations (see Section 2.3) and via language instruction COUPDEF for user-defined couplings (see Section 2.2.1).

   In addition, coupling characteristics “Type of coupling” and “Block change response” can be altered for fixed coupling configurations by means of language instruction COUPDEF.

**Change protection for coupling characteristics**

Channel-specific MD: COUPLE_IS_WRITE_PROT_1 is set to define whether or not the configured coupling parameters “Speed ratio”, “Type of coupling” and “Block change response” can be altered by the NC part program:

0: Coupling parameters can be altered by the NC part program with COUPDEF.

1: Coupling parameters cannot be altered by the NC part program. Attempts to make changes will be rejected with an alarm message.

**Overlaid movement**

In synchronous operation, the synchronous spindle copies the movement of the leading spindle in accordance with the programmed speed ratio.

At the same time, the synchronous spindle can also be traversed with overlay so that the LS and FS can operate at a specific angular position in relation to one another.

The overlaid traversing movement of the FS can be initiated in various ways:

1. Programmable position offset of FS in AUTOMATIC and MDA:
   
   The position reference between LS and FS can be altered in active synchronous operation with language instructions COUPON and SPOS (see Section 2.1.2)
2. Manual position offset of FS:
   - In JOG operating mode (continuous JOG or incremental JOG): Overlay of FS by handwheel or plus or minus traversing key in active synchronous operation.
   - In AUTOMATIC and MDA operating modes: Overlay of FS by handwheel via DRF offset

As soon as the FS executes the overlaid traversing movement, the IS “Overlaid movement” (DB31, DBX98.4) is set to “1”. The overlaid movement is executed optimally in terms of time at the maximum possible FS speed. With offset change by SPOS, the positioning speed can be set with FA[Sn] and influenced with override (selection possibility with DB31, DBX17.0).

References: /FB/, S1, “Spindles”

2.1.2 Selecting synchronous mode

Activation of coupling
Language instruction COUPON activates the coupling between the programmed spindles with the last valid parameters and thus also activates synchronous mode. This coupling may be a fixed configuration or user-defined. The leading spindle and/or following spindle may be at standstill or in motion at the instant of activation.

Certain conditions must be fulfilled before synchronous operation can be activated (see Section 2.1.4).

Activation methods
Two different methods can be selected to activate synchronous mode:
1. Fastest possible activation of coupling with any angular reference between leading and following spindles.
   COUPON(FS, LS)
2. Activation of coupling with a defined angular offset POSFS between leading and following spindles. With this method, the angular offset must be programmed on selection.
   COUPON(FS, LS, POSFS)

Note
If the LS and/or FS is in axis mode before switching on the synchronous coupling, the axis mode is left and spindle mode is activated with use of the spindle identifier with SW 3.2 and higher.

If the spindle is switched on with use of the axis identifier, no changeover takes place.

Block change response
Before synchronous operation is selected, it must be determined under what conditions the block change must occur when synchronous mode is activated (see Section 2.2.1).
Determining current coupling status

It is possible to determine the current coupling status for the specified axis/spindle in the NC part program by means of axial system variable $AA_COUP_ACT[<axial expression>]\) (see Section 2.2.3 Axis system variables for synchronous spindle). As soon as the synchronous spindle coupling is active for the following spindle, bit 2 must be “1” when read.

Change defined angular offset

Language instructions COUPON and SPOS allow the defined angular offset to be changed while synchronous mode is active. The following spindle is positioned as an overlaid movement at the angular offset programmed with $POSFS$. IS “Overlaid movement” (DB31, ... DBX98.4) is set during this period.

Angular offset $POSFS$

The defined angular offset $POSFS$ must be specified as an absolute position referred to the zero degrees position of the leading spindle in a positive direction of rotation.

The “Zero degrees position” of a position-controlled spindle is calculated from the zero mark signal or Bero signal of the measuring system and the offsets stored in axis-specific machine data (MD: REFP_SET_POS, REFP_MOVE_DIST, REFP_MOVE_DIST_CORR)

Range of $POSFS$: 0 ... 359.999 degrees.

References: /FB/, R1, “Reference Point Approach”

Read current angular offset

Using axial system variables, it is possible to read the current position offset between the FS and LS in the NC part program. The following two position offsets exist:

a) Current position offset of setpoint between FS and LS

\[
$AA_COUP_OFFS[<axis identifier for FS>]\]

b) Current position offset of actual value between FS and LS

\[
$VA_COUP_OFFS[<axis identifier for FS>]\]

(For more information about <axis identifier>, see Section 2.1.1)

Activation after POWER ON

Synchronous operation can also be activated for LS or FS which are not referenced/synchronized (IS: “Referenced/synchronized 1 or 2” DB31, ... DBX60.4 or DBX60.5 = 0). In this case, a warning message is displayed.

Example: LS and FS are already coupled in a friction lock via a workpiece after power ON.

2.1.3 Deselecting synchronous mode

Deactivation of coupling

Language instruction COUPOF cancels synchronous mode between the programmed spindles. The coupling concerned can be a fixed configuration or user-defined. The leading and following spindles can be at standstill or in motion when synchronous operation is deactivated.

On switching off the synchronous mode, the following spindle is put into control mode. The originally programmed S-word is no longer valid for the FS, the following spindle can be operated like any other normal spindle.
When the coupling is deactivated, a block preprocessing stop (STOPRE) is generally initiated internally in the control.

**Deactivation while spindles are moving**

If synchronous mode is deselected while the spindles are in motion, the following spindle continues to rotate at the current speed ($n_{FS}$). The current speed can be read with system variable $AA\_S$ in the NC part program.

The spindle can then be stopped from the part program with M05, SPOS or SPOSA or from the PLC with the appropriate interface signal.

**Deselection methods**

Three different methods can be used to deselect synchronous mode:

1. Fastest possible deactivation of coupling.
   The block change is enabled immediately.
   \(\text{COUPOF}(\text{FS}, \text{LS})\)

2. The coupling is not deselected until the following spindle has overtraveled the programmed deactivation position \(\text{POS}_{FS}\).
   The block change is then enabled.
   \(\text{COUPOF}(\text{FS}, \text{LS}, \text{POS}_{FS})\)

3. The coupling is not deselected until the following spindle and the leading spindle have overtraveled the programmed deactivation positions \(\text{POS}_{FS}\) and \(\text{POS}_{LS}\).
   The block change is then enabled.
   \(\text{COUPOF}(\text{FS}, \text{LS}, \text{POS}_{FS}, \text{POS}_{LS})\)

**Note**

If the LS and/or FS is in axis mode before switching off the synchronous coupling, the axis mode is left with use of the spindle identifier and the speed control mode is activated with SW 3.2 and higher.

If the spindle is switched off with use of the axis identifier, no changeover takes place. Before shutdown, the LS must be in the setpoint-side standstill.

**POS\(_{FS}\), POS\(_{LS}\)**

The deactivation positions \(\text{POS}_{FS}\) and \(\text{POS}_{LS}\) correspond to the actual positions of the FS and LS referred to the defined reference point value (see Section 2.1.2).

Range of \(\text{POS}_{FS}, \text{POS}_{LS}\): 0...359.999 degrees.

**References**: /FB/, R1, “Reference Point Approach”
2.1.4 Prerequisites for synchronous mode

The following conditions must be fulfilled before the synchronous spindle coupling is activated or else alarm messages will be generated.

- The synchronous spindle coupling must have been defined beforehand (either a fixed configuration via machine data or according to user definition via part program).

- The spindles to be coupled must be defined in the NC channel in which the coupling is activated.
  
  Channel-specific MD 20070: AXCONF_MACHAX_USED  
  Axis-specific MD 35000: SPIND_ASSIGN_TO_MACHAX

- The following spindle must be assigned to the NC channel in which the coupling is activated.
  
  Default setting with axis-specific MD30550: AXCONF_ASSIGN_MASTER_CHAN

- LS and FS must be equipped with at least one position measuring system for position sensing.

- If the FS is in speed control mode (IS “Position controller active” DB31, ... DBX61.5 = 0) before synchronous operation is activated, it must be switched to position control with language instruction SPCON.

**Note**

When position control is activated, the maximum setpoint speed of the LS is automatically limited to 90% (control reserve) of the maximum speed as determined by the limit frequency of the position encoder. The limitation is reported via IS “Setpointspeed limited” (DB31, ... DBX83.1).

After deactivation of synchronous operation, position control mode can be deselected again with language instruction SPCOF.

**References**: /FB/, S1, “Spindles”

- To ensure more accurate synchronization, the LS should be in position control mode (language instruction SPCON) before the coupling is activated, thus allowing a setpoint coupling to be established between the LS and FS. Actual-value coupling is always possible if there is a measuring system for the LS.

- Before selecting the synchronous mode, the gear stage necessary for FS and LS must be selected. In synchronous mode, gear stage changeover and therefore oscillation mode are not possible for FS and LS. Upon request, an alarm message is generated.

- If FS and/or LS are in the axis mode and if they are actuated with a spindle identifier, spindle mode is activated. The VDI interface signals for the spindle concerned are modified, the active parameter block is changed over and feedforward control is activated.

  If the spindle is activated with use of the axis identifier, no changeover takes place.
Cross-channel coupling (SW4)

- The LS can be programmed either via a part program, PLC (FC18) or, in SW 4 and higher, by means of synchronized actions.

Note

If the LS is swapped between channels with activated speed coupling, and the sequence of the channels is changed, the coupling must be deactivated.

Example:
Channel 1:
Channel 2:
Channel 3: FS in channel 3. COUPON active
Channel 4:
Channel 5:

Easy exchange possible for the LS between:
Channel 1 ←→ Channel 2,
Channel 1 ←→ Channel 3,
Channel 2 ←→ Channel 3,
Channel 4 ←→ Channel 5

Exchange possibilities for LS, where the coupling must be deactivated:
from channel 1 ←→ channel 4,
from channel 2 ←→ channel 4,
from channel 3 ←→ channel 4,
from channel 1 ←→ channel 5,
from channel 2 ←→ channel 5,
from channel 3 ←→ channel 5

SW 5 and higher

The LS can belong to any channel.
- The LS can be exchanged between channels by means of “Axis exchange”.
- When several following spindles are coupled to one leading spindle, the dynamic response of the coupling is determined by the weakest response as a function of the coupling factor. The acceleration rate and maximum speed are reduced for the leading spindle to such a degree that none of the coupled leading spindles can be overloading.

2.1.5 Monitoring of synchronous operation

Fine/coarse synchronism

In addition to conventional spindle monitoring operations, synchronous operation between the FS and LS is also monitored in synchronous mode.

In this case, IS: “Fine synchronism” (DB31, ... DBX98.0) or “Coarse synchronism” (DB31, ... DBX98.1) is transmitted to the PLC to indicate whether the current position (AV, DV) or actual speed (VV) of the following spindle is within the specified tolerance window.
When the coupling is switched on, the signals “Coarse synchronism” and “Fine synchronism” are updated with reaching of the setpoint-side synchronism.

The size of the tolerance windows is set with MD of the FS.

Reaching of the synchronism is influenced by the following factors:

- AV, DV: Position deviation between FS and LS
- VV: Speed difference between FS and LS

Example of part program:

```
M3 S500 M2=5
G4 F10
COUPON(S2, S1)
Z10
WAITC(S2, “Fine”)
M55
```

Fig. 2-1 Synchronism monitoring with COUPON and synchronism test marker WAITC
Threshold values

The relevant position or velocity tolerance range for the following spindle in relation to the leading spindle must be specified in degrees of rev/min.

- Threshold value for “Coarse synchronism”
  axis spec. MD 37200: AV, DV: COUPLE_POS_TOL_COARSE
  MD 37220: VV: COUPLE_VELO_TOL_COARSE

- Threshold value for “Fine synchronism”
  axis spec. MD 37210: AV, DV: COUPLE_POS_TOL_FINE
  MD 37230: VV: COUPLE_VELO_TOL_FINE

Speed/acceleration limits

In synchronous mode, the speed and acceleration limit values of the leading spindle are adjusted internally in the control in such a way that the following spindle can imitate its movement, allowing for the currently selected gear stage and effective speed ratio, without violating its own limit values.

For example, the LS is automatically decelerated to prevent the FS from exceeding the maximum speed in order to maintain synchronism between the spindles.

2.2.1 Preparatory programming instructions

User-defined coupling (SW 4 and earlier)

Up to two synchronous spindle couplings can be active simultaneously in each channel (SW 4 and earlier). Provided no fixed coupling configuration has been programmed, both couplings can be freely defined by the NC part program.

These couplings must also be parameterized by the NC part program. Default values are used for parameters which are not programmed.

A new synchronous spindle coupling is defined if an FS/LS coupling relationship which has no fixed configuration is programmed in language instruction COUPEDEF. This coupling can be invalidated again with language instruction COUPDEL if, for example, a further synchronous spindle coupling between other spindles is needed. These programming options, i.e. re-definition and deletion of couplings, allow more than two coupling relationships to be successively created in the NC channel (SW 4 and earlier).

SW 5 and higher

Any number of couplings can be programmed. Furthermore, one coupling can also be configured via machine data as in earlier SW versions.

Permanent coupling configuration

The coupling characteristics and speed ratio for a permanently configured synchronous spindle coupling can be altered by the NC part program provided that they are not write-protected. The machine axes for LS and FS cannot be changed.

Define new couplings

Language instruction “COUPEDEF” can be used to create new synchronous spindle couplings (user-defined) and to modify the parameters for existing couplings.

When the coupling parameters are fully specified, the following applies:

COUPEDEF (FS, LS, \(\hat{U}_{\text{numerator}}\), \(\hat{U}_{\text{denominator}}\), block change response, coupling type)

The spindle coupling is unambiguously defined with FS and LS which must be programmed for every COUP... instruction. Alarm messages will otherwise be generated.
The other coupling parameters must only be programmed when they need to be changed. The last valid status remains applicable for non-specified parameters.

The individual coupling parameters are explained below:

- **FS, LS**: Axis identifiers for following and leading spindles
e.g.: S1, SPI(1), S2, SPI(2)
The applicable spindle number must be assigned to a machine axis in axis-specific MD: SPIND_ASSIGN_TO_MACHAX.

- **Ü\textsubscript{numerator}, Ü\textsubscript{denominator}**: Speed ratio parameters for numerator and denominator
The speed ratio is input in the form of numeric values for numerator and denominator (see Section 2.1.1).
The numerator must always be programmed. If no denominator is specified, then its value is always assumed to be “1,0”.

- **Block change response**
This parameter allows the condition for block change on selection of synchronous operation to be defined:

  - NOC  \Rightarrow Block change is immediately enabled
  - FINE  \Rightarrow Block change in response to “Fine synchronism”
  - COARSE  \Rightarrow Block change in response to “Coarse synchronism”
  - IPOSTOP  \Rightarrow Block change in response to IPOSTOP (e.g. after setpoint-based synchronism)

The block change response is entered as a character string (i.e. with quotation marks).
The block change response can be specified simply by writing the letters in bold print. The remaining letters can be entered to improve legibility of the part program but they are not otherwise significant.

If no block change response is specified, then the currently selected response continues to apply.

With the programmable synchronism test marks WAITC, the replacement with new blocks is delayed until reaching the synchronism indicated.

- **Type of coupling**

  - DV (Desired Values)  \Rightarrow Setpoint coupling between FS and LS
  - AV (Actual Values)  \Rightarrow Actual-value coupling between FS and LS
  - VV (Velocity Values)  \Rightarrow Speed coupling between FS and LS

If no coupling type is specified, then the currently selected type continues to apply.

---

**Note**
The coupling type may only be changed when synchronous operation is deactivated!
2.2 Programming of synchronous spindle couplings

**Examples**

COUPDEF (SPI(2), SPI(1), 1.0 , 1.0, “FINE”, “DV”)
COUPDEF (S2, S1, 1.0 , 4.0)
COUPDEF (S2, SPI(1), 1.0)

**Default settings**

The following default settings apply to user-defined couplings:

- $\hat{u}_{\text{numerator}} = 1.0$
- $\hat{u}_{\text{denominator}} = 1.0$
- Block change response = IPOSTOP (block change enabled with setpoint synchronism)
- Type of coupling = DV (setpoint coupling)

**Delete couplings**

Language instruction “COUPDEL“ is used to delete user-defined couplings.

COUPDEL (FS, LS)

**SW 4 and earlier**

If a new synchronous spindle coupling relationship needs to be defined and all available, freely configurable couplings (1 or 2) are already configured, then one of the couplings will have to be deleted first.

**SW 5 and higher**

There is no limit to the number of programmable couplings. The COUPDEL command can be used, but is not absolutely necessary.

An alarm message is generated if COUPDEL is programmed for an active coupling. Synchronous operation remains active. It must be deselected beforehand with COUPOF.

**Note**

A fixed coupling configuration cannot be deleted with COUPDEL!

**Activate original coupling parameters**

Language instruction “COUPRES“ can be used to re-activate the configured coupling parameters.

COUPRES (FS, LS)

The parameters programmed with COUPDEF (including speed ratio) are then overwritten.

Language instruction “COUPRES“

- activates the parameters stored in the machine and setting data (fixed coupling configuration) and
- activates the default settings (user-defined coupling).
2.2 Programming of synchronous spindle couplings

Programmable block change

With Software Version 3.2 and higher, it is possible to mark a point in the NC program using "WAITC". The system waits at this point for fulfillment of the synchronism conditions for the specified FS and delays changes to new blocks until the specified state of synchronism is reached (see Fig. 2-1).

**WAITC (FS)**

Advantage: The time between switching on the synchronous coupling and reaching the synchronism can be technologically useful.

**Note**

Basically, it is always possible to write WAITC. If the spindle indicated is not active as FS, the instruction for this spindle is without effect.

If no synchronism condition is indicated, the check is always performed for the synchronism condition programmed/configured on the respective coupling, at least for the setpoint synchronism.

Examples

- WAITC(S2)
- WAITC(S2, "Fine")
- WAITC(S2, ,S4, "Fine")

### 2.2.2 Programming instructions for activating and deactivating the coupling

Activate synchronous mode

Language instruction COUPON is used to activate couplings and synchronous mode.

Two methods by which synchronous operation can be activated are available:

1. **COUPON(FS, LS)**
   Fastest possible activation of synchronous operation with any angular reference between the leading and following spindles.

2. **COUPON(FS, LS, POSFS)**
   Activation of synchronous operation with a defined angular offset POSFS between the leading and following spindles. This offset is referred to the zero degrees position of the leading spindle in a positive direction of rotation. The block change is enabled according to the defined setting. Range of POSFS: 0 ... 359.999 degrees.

By programming COUPON(FS, LS, POSFS) or SPOS when synchronous operation is already active, the angular offset between LS and FS can be changed.

Deactivate synchronous mode

Three different methods can be selected to deactivate synchronous mode:

1. **COUPOF(FS, LS)**
   Fastest possible deactivation of synchronous operation. Block change is immediately enabled.
2. **COUPOF(FS, LS, POSFS)**
   Deselection of synchronous operation after deactivation position POSFS has been overtraveled. Block change is not enabled until this position has been overtraveled.

3. **COUPOF(FS, LS, POSFS, POSLS)**
   Deselection of synchronous operation after the two deactivation positions POSFS and POSLS have been overtraveled. Block change is not enabled until both positions have been overtraveled.
   Range of POSFS, POSLS: 0...359.999 degrees.

If continuous path control (G64) is programmed, a non-modal stop is generated internally in the control.

Examples

- COUPDEF (S2, S1, 1.0, 1.0, “FINE”, “DV”) : COUPOF (S2, S1, 0) : COUPDEL (S2, S1)

### 2.2.3 Axis system variables for synchronous spindle

**Reading the current coupling status**

The current coupling status for the following spindle can be read in the NC part program with the following axis system variable:

\[ $AA\_COUP\_ACT[<\text{axial expression}>] \]

(Explanation about `<axial expression>`, see Section 2.1.1)

**Example**

\[ $AA\_COUP\_ACT[SPI(2)] \]

The value read has the following significance for the following spindle:
Byte = 0: No coupling active
Bit 2 = 1: Synchronous spindle coupling active

**Read current angular offset**

The current position offset between the FS and LS can be read in the NC part program by means of the following axial system variables:

a) Setpoint-based position offset between FS and LS:

\[ $AA\_COUP\_OFFS[<\text{axial expression}>] \]

b) Actual-value-based position offset between FS and LS:

\[ $VA\_COUP\_OFFS[<\text{axial expression}>] \]

**Example**

\[ $AA\_COUP\_OFFS[S2] \]

If an angular offset is programmed with COUPON, this coincides with the value read after reading the setpoint synchronism.
2.2 Programming of synchronous spindle couplings

---

**Note**

After cancellation of the servo enable signal when synchronous operation and follow-up mode are active, the position offset applied when the controller is enabled again is different to the originally programmed value. In this case, the altered position offset can be read and corrected in the NC part program if necessary.
2.3 Configuration of a synchronous spindle pair via machine data

**Coupling parameters**

One synchronous spindle coupling per NC channel can be configured permanently via machine data.

It is then necessary to define the machine axes (spindles) which are to be coupled and what characteristics this coupling should have.

The following parameters can be configured as fixed settings for the synchronous spindle coupling:

- **Synchronous spindle pair** (channel-specific MD: COUPLE_AXIS_1[n])
  This machine data defines the two machine axes which are to form the synchronous spindle pair (following spindle (n=0), leading spindle (n=1)).
  A “0” as the setting for the axis number means that no coupling is configured via the machine data. The machine data for the coupling characteristics are then irrelevant.
  The machine axis numbers for the LS and FS can not be changed by the NC part program for a configured coupling configuration.

- **Speed ratio**
  This ratio is input in the form of numerator and denominator via setting data (currently POWER ON active!) in two speed parameters (channel-specific SD: COUPLE_RATIO_1[n]). The quotient is generated internally in the control.

\[
k = \frac{\text{Speed ratio parameter nominator}}{\text{Speed ratio parameter denominator}} = \frac{\$SC\_COUPLE\_RATIO[0]}{\$SC\_COUPLE\_RATIO[1]}
\]

Provided it is not write-protected, the speed ratio can be changed by the NC part program with language instruction COUPDEF.

- **Block change response** (channel-specific MD: COUPLE_BLOCK_CHANGE_CTRL_1)
  One of the following options can be selected as the condition for a block change:
  0: Block changes immediately
  1: Block change in response to “Fine synchronism”
  2: Block change in response to “Coarse synchronism”
  3: Block change in response to IPOSTOP (i.e. after setpoint-based synchronism)

- **Type of coupling** between LS and FS: (channel-specific MD: COUPLING_MODE_1)
  0: Actual-value coupling
  1: Setpoint coupling
  2: Speed coupling

- **Abortion of coupling with NC start**
  Channel-specific MD: COUPLE_RESET_MODE_1 (see Table 2-3)
2.3 Configuration of a synchronous spindle pair via machine data

- **Write-protection for coupling parameters:**

  (channel-specific MD: COUPLE_IS_WRITE_PROT_1)

  It can be defined in this machine data whether or not the configured coupling parameters “Speed ratio”, “Type of coupling” and “Block change response” may be influenced by the NC part program.

  0: Coupling parameters can be changed by the NC part program

  1: Coupling parameters cannot be changed by the NC part program. Attempts to make changes are rejected with an alarm message.

2.3.1 Configuration of the behavior with NC start

The response to NC machining program start is defined by the channel-specific machine data.

<table>
<thead>
<tr>
<th>Configured coupling</th>
<th>Programmed coupling (see Section 2.3)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Coupling is maintained</td>
<td>MD: COUPLE_RESET_MODE  Bit 0 = 0</td>
</tr>
<tr>
<td>Deselect coupling</td>
<td>MD: COUPLE_RESET_MODE  Bit 0 = 1</td>
</tr>
<tr>
<td>Activate configured data</td>
<td>Bit 5 = 1</td>
</tr>
<tr>
<td>Switch on coupling</td>
<td>Bit 9 = 1</td>
</tr>
</tbody>
</table>

2.3.2 Configuration of the behavior with Reset

With SW 3.2 and higher, the following behavior can be set with the channel-specific machine data with reset and end of NC machining program:

<table>
<thead>
<tr>
<th>Configured coupling</th>
<th>Programmed coupling (see Section 2.3)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Coupling is maintained</td>
<td>MD: COUPLE_RESET_MODE  Bit 1 = 0</td>

<tr>
<td>Deselect coupling</td>
<td>MD: COUPLE_RESET_MODE  Bit 1 = 1</td>
</tr>
<tr>
<td>Activate configured data</td>
<td>MD: COUPLE_RESET_MODE  Bit 6 = 1</td>
</tr>
</tbody>
</table>
2.4 Special features of synchronous operation

2.4.1 Special features of synchronous operation in general

Control dynamics
When a setpoint coupling is used, the position controller parameters of FS and LS (e.g. \(K_V\) factor) must be matched. It may be necessary to activate different parameter sets for speed control mode and synchronous operation (M41...M45).

Feedforward control
Due to the improved control system dynamic response it provides, feedforward control is always active for the following and leading spindles in synchronous mode. It can, however, be deselected for FS and LS with axis-specific MD: FFW_MODE (=0). The NC part program cannot deactivate the feedforward control for LS and FS with FFW_OF.

The feedforward control mode (speed or torque feedforward control) is defined in axis-specific MD: FFW_MODE.

References: /FB/, K3, “Compensations”

Speed/acceleration limits
The speed and acceleration limits of the spindles operating in synchronous mode are determined by the “weakest” spindle in the coupling. The current gear stages, the programmed acceleration and, for the leading spindle, the effective position control status (On/Off) are taken into account for this purpose.

As an example, the maximum speed of the leading spindle is calculated internally in the control on the basis of the speed ratio and the spindle limitations of the following spindle.

Multiple couplings
If the system detects that a coupling is already active for an FS and LS when synchronous mode is activated, then the activation process is ignored and an alarm message generated.

Example of multiple couplings:
- A spindle is acting as the FS for several LS

SW 5.1 and later
Number of configurable spindles per channel:
- Every axis in the channel can be configured as a spindle. The number of axes per channel is dependent on the control system model.
2.4 Special features of synchronous operation

**SW 5.2 and later**
Cross-channel setpoint linkage and optional number of following spindles in optional channels of an NCU:

- Cross-channel synchronous spindle setpoint links (DV) can be implemented with no additional restrictions.
- Any number of following spindles in any channels on an NCU can be coupled to one leading spindle.

**Number of following spindles to one leading spindle**
In SW 5.2 and later, any number of following spindles in any channels on an NCU can be coupled to one leading spindle. The only possible restriction to the number of spindles could be imposed by the real CPU time requirement.

The dynamic response of a coupling group is determined by the weakest response as a function of the coupling factor. The acceleration rate and maximum speed are reduced for the leading spindle down to the load limit of the coupled leading spindles.

Further notes: See above Speed/acceleration limits

**Knee-shaped acceleration characteristic**
The effect of a knee-shaped acceleration characteristic (identified by axis-specific MD: ACCEL_REDUCTION_SPEED_POINT and ACCEL_REDUCTION_FACTOR) on the following spindle is taken into account for the leading spindle.

The acceleration should, however, be constant over the entire speed range for the following spindle. If a knee-shaped acceleration characteristic is nevertheless stored in the above-mentioned machine data for the following spindle, the knee-shaped acceleration characteristic for the LS must be set such that the FS is not overloaded in acceleration terms or that the programmed acceleration for the LS is used accordingly.

**Direct control of synchronous mode by PLC**
ASUBs (activation of asynchronous subprograms) processed by the PLC can be used to activate or terminate synchronous mode at any chosen time in the AUTOMATIC or MDA modes.

**Response to alarms**
When alarms (e.g. servo alarms) occur during synchronous operation which cause cancellation of the servo enable signal in the control and active follow-up mode, the subsequent response is the same as if IS “Servo enable” (DB31, ... DBX2.1) had been cancelled by the PLC (and IS “Follow-up mode” (DB31, ... DBX1.4) is set) → see Section 2.4.2 .
2.4.2 Influence on synchronous operation via PLC interface

PLC interface signals

In synchronous operation, the influence of the PLC on the coupling resulting from the setting of LS and FS interface signals must be noted.

The effect of the main PLC interface signals on the synchronous spindle coupling is described below.

Spindle speed override (DB31, ... DBB19)

The spindle speed override value input by the PLC in synchronous operation is applied only to the leading spindle.

Axis/spindle disable (DB31, ... DBX1.3)

The participating axes behave as shown in the following table (SW 4 and higher):

<table>
<thead>
<tr>
<th>No.</th>
<th>LS/LA</th>
<th>FS/FA</th>
<th>Coupling</th>
<th>Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>0</td>
<td>Off</td>
<td>Axis setpoints are output</td>
</tr>
<tr>
<td>2</td>
<td>0</td>
<td>1</td>
<td>Off</td>
<td>no setpoint output for FS/FA</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
<td>0</td>
<td>Off</td>
<td>no setpoint output for LS/LA</td>
</tr>
<tr>
<td>4</td>
<td>1</td>
<td>1</td>
<td>Off</td>
<td>no setpoint output for LS/LA and FS/FA</td>
</tr>
<tr>
<td>5</td>
<td>0</td>
<td>0</td>
<td>On</td>
<td>Axis setpoints are output</td>
</tr>
<tr>
<td>6</td>
<td>0</td>
<td>1</td>
<td>On</td>
<td>Disable not effective for FS/FA</td>
</tr>
<tr>
<td>7</td>
<td>1</td>
<td>0</td>
<td>On</td>
<td>Disable also effective for FS/FA</td>
</tr>
<tr>
<td>8</td>
<td>1</td>
<td>1</td>
<td>On</td>
<td>no setpoint output for LS/LA and FS/FA</td>
</tr>
</tbody>
</table>

- The signal is not effective for the FS/FA when the coupling is active. → No. 6
- If the signal for the LS/LA is enabled, this also acts on FS/FA(s), → No. 7
- If a workpiece is clamped between two spindles (transfer of workpiece from front face to rear face machining), it cannot be damaged.

Servo enable (DB31, ... DBX2.1)

Cancellation of “Servo enable” for LS (either via PLC interface or internally in control in the event of faults):

If the servo enable signal of the LS is set to “0” during synchronous operation and a setpoint coupling is active, a switchover to actual-value coupling is executed in the control. If the LS is in motion at this instant, it is decelerated to a standstill and an alarm message generated. Synchronous operation remains active.

Cancellation of “Servo enable” for FS in synchronous operation (either via PLC interface or internally in control in the event of faults):

The coupling is internally cancelled until the signals are reset.
If the “Servo enable” signal is not set for either of the spindles when synchro-
nous operation is selected, synchronous operation is still activated when the
coupling is switched on. The LS and FS however remain at standstill until the
servo enable signal is set for both of them.

Setting the “Servo enable” signal for LS and FS:
When the signal edge of IS “Servo enable” switches to 1, the spindle either
moves back to the old position (position on cancellation of servo enable) (signal
status = 0: Stop active) or the current positions (position offset) are used again
(signal status = 1: Follow-up active), depending on IS “Follow-up mode”.

---

**Note**

If the “servo enable” signal is cancelled for the FS after Spindle Stop without
the coupling being deactivated beforehand, then any synchronism error result-
ing from external intervention (e.g. manual rotation) will not be compensated
when the “servo enable” signal is applied again.

This may result in loss of the defined angular reference between the FS and LS
for special applications.

---

**Follow-up mode** *(DB31, ... DBX1.4)*

Interface signal “Follow-up mode” is relevant only if the “servo enable” for the
drive is cancelled. When “servo enable” is set for the FS and LS, either the
spindle will return to the position recorded on cancellation of the servo enable
signal (signal state = 0: Stop active) or the current positions will be used again
(signal status = 1: Follow-up active), depending on IS “Follow-up mode”.

---

**Position measuring system**

1/2 *(DB31, ... DBX1.5 and 1.6)*

Switchover between the position measuring systems for the FS and LS is not
locked out in synchronous operation. A switchover would not affect the cou-
pling. It is however recommended that the measuring systems only be switched
when synchronous mode is not active.

If “Park” status is selected for the FS or LS in synchronous operation, then the
system responds as if “servo enable” had been cancelled.

---

**Spindle Reset**

(delete distance to go) *(DB31, ... DBX2.2)*

When Spindle Reset is set for the LS in synchronous operation, the LS is
braked down to standstill at the selected acceleration rate. The FS and LS con-
tinue to operate in synchronous mode. The overlaid motion (except with
COUP...) is terminated as quickly as possible.

---

**Spindle Stop**

(Feed Stop) *(DB31, ... DBX4.3)*

When “Spindle Stop” is set for the FS or LS, both coupled spindles are braked
down to standstill via a ramp, but continue to operate in synchronous mode.
As soon as IS “Spindle Stop” is no longer active for any of the spindles in the
coupling, it is accelerated back up to the previous speed setpoint.

**Application**

“Spindle Stop” can halt the synchronous spindle pair without offset since the
servo loop remains operative.
Example

When the protective door is opened with an active synchronous spindle coupling, the FS and LS must be stopped without the coupling relationship being altered. This can be achieved by applying IS “Spindle Stop” to halt the FS and LS (IS “Axis/spindle stationary” (DB31, ... DBX61.4) = 1). “Servo enable” can then be cancelled for both spindles.

Delete S value (DB31, ... DBX16.7)

The S value programmed for the LS is deleted and the LS decelerated down to zero speed via a ramp. The FS and LS continue to operate in synchronous mode.

Notes

IS “Delete S value” has no affect on the FS in synchronous operation.

Re-synchronize spindle 1/2 (DB31, ... DBX16.4 and 16.5)

It is possible to synchronize the spindle (LS) with its positioning measuring system when it is operating in synchronous mode. It is however recommended that the leading spindle only be re-synchronized when synchronous mode is not active.

Traversing keys in JOG (DB31, ... DBX4.6 and 4.7)

The “plus and minus traversing keys” for JOG are not disabled internally for the FS in synchronous operation, i.e. the FS executes an overlaid motion if one of these keys is pressed.

Note

If overlaid traversing movements are to be precluded, they must be locked out by measures in the PLC user program.

NC Stop axes plus spindles (DB21, ... DBX7.4)

“NC Stop axes plus spindles” in synchronous operation decelerates the coupled spindles in accordance with the selected dynamic response. They continue to operate in synchronous mode.

NC Start (DB21, ... DBX7.1)

See Section 2.3.1.

Note

NC Start after NC Stop does not deselect synchronous operation.
2.4.3 Special points regarding start-up of a synchronous spindle coupling

**Spindle start-up**

The leading and following spindles must be started up initially like a normal spindle. This start-up procedure is described in:

**References**: /IAD/, SINUMERIK 840D Installation and Start-Up Guide and

**References**: /FB/, S1, “Spindles”

**Parameters**

The following parameters must then be set for the synchronous spindle pair:

- The machine axis numbers for the leading and following spindles (for a permanently configured coupling with channel-spec. MD: COUPLE_AXIS_1[n])
- The required coupling type (setpoint, actual-value or velocity coupling) (for a permanently configured coupling with channel-spec. MD: COUPLE_MODE_1[n])
- The gear stage(s) of FS and LS for synchronous operation
- Plus the following coupling properties (see Section 4.1) for a permanently configured synchronous spindle coupling:
  - Block change behavior in synchronous spindle operation
    Channel-spec. MD: COUPLE_BLOCK_CHANGE_CTRL_1
  - Coupling abort behavior
    Channel-spec. MD: COUPLE_RESET_MODE_1
  - Modification protection for coupling parameters
    Channel-spec. MD: COUPLE_IS_WRITE_PROT_1
  - Speed ratio parameters for synchronous spindle coupling
    Channel-spec. SD: COUPLE_RATIO_1[n]

**Response to setpoint changes**

In order to obtain the best possible synchronism in setpoint couplings, the FS and LS must have the same dynamic response to setpoint changes. Each of the axial servo loops (position, speed and current controller) should be set optimally to eliminate any interference as quickly and efficiently as possible. The dynamic response adaptation function in the setpoint branch is used to match axial dynamic responses without loss of control quality.

The following control parameters must each be set optimally for the FS and LS:

- K<sub>y</sub> factor (MD 32200 POSCTRL_GAIN)
- Feedforward control parameters
  MD 32620 FFW_MODE
  MD 32610 VELO_FFW_WEIGHT
  MD 32650 AX_INERTIA
  MD 32800 EQUIV_CURRCTRL_TIME
  MD 32810 EQUIV_SPEEDCTRL_TIME
2.4 Special features of synchronous operation

References: /FB/, K3, “Compensations”

The following control parameters must be set identically for the FS and LS:

- Fine interpolator type (MD 33000: FIPO_TYPE)
- Axial jerk limitation
  MD 32400 AX_JERK_ENABLE
  MD 32410 AX_JERK_TIME
  MD 32420 JOG_AND_POS_JERK_ENABLE
  MD 32430 JOG_AND_POS_MAX_JERK

References: /FB/, G2, “Velocities, Setpoint/Actual Value Systems, Closed-Loop Control”

Dynamic response adaptation

The FS and the coupled LS must have the same dynamic response to setpoint changes. The “same dynamic response” means that their following errors must be equal at any given speed.

The dynamic response adaptation function in the setpoint branch is capable of accurately matching the response to setpoint changes on dynamically unequal axes (servo loops). The difference in the equivalent time constants between the dynamically “weakest” spindle and the other spindle in the coupling must be entered as the dynamic response adaptation time constant.

With active speed feedforward control, the dynamic response is mainly determined by the equivalent time constants of the “slowest” speed control loop.

Leading spindle: MD 32810: EQUIV_SPEEDCTRL_TIME [n] = 5ms
Following spindle: MD 32810: EQUIV_SPEEDCTRL_TIME [n] = 3ms
→ Time constant of dynamic response adaptation for following spindle:
  MD 32910: DYN_MATCH_TIME [n] = 5ms – 3ms = 2ms

The dynamic response adaptation must be activated axially via MD 32900 DYN_MATCH_ENABLE.

The dynamic adaptation setting can be checked by comparing the following errors of the FS and LS (in Diagnosis operating area; Service Axes display). Their following errors must be identical when they are operating at the same speed!

By way of fine adjustment, it may be necessary to slightly adjust Ky factors or feedforward control parameters in order to achieve an optimum result.

Control parameter sets

A separate parameter set with servo loop setting is assigned to each gear stage on coupled spindles.

These parameter sets can be used, for example, to adapt the dynamic response of the leading spindle to the following spindle in synchronous operation. When the coupling is deactivated (speed or positioning mode), it is therefore possible to select other position controller parameters for the FS and LS. To utilize this option, a separate gear stage must be reserved for synchronous operation and selected before synchronous mode is activated.

References: /FB/, G2, “Velocities, Setpoint/Actual Value Systems, Closed-Loop Control”
### Actual-value coupling

In an actual-value coupling, the drive for the FS must be considerably more dynamic than the leading spindle drive. The individual drives in an actual-value coupling are also set optimally according to their dynamic response.

An actual-value coupling should only be used in exceptional cases.

### Velocity coupling

The velocity coupling corresponds internally to a setpoint coupling, but with lower dynamic requirements of the FS and LS. A servo loop is not needed for the FS and/or LS and no measuring systems are needed.

### Threshold values for coarse/fine synchronism

After controller optimization and feedforward control setting, the threshold values for coarse and fine synchronism must be entered for the FS.

- Threshold value for "Coarse synchronism"
  
  axis spec. MD 37200: AV, DV: COUPLE_POS_TOL_COARSE
  MD 37220: VV: COUPLE_VELO_TOL_COARSE

- Threshold value for "Fine synchronism"
  
  axis spec. MD 37210: AV, DV: COUPLE_POS_TOL_FINE
  MD 37230: VV: COUPLE_VELO_TOL_FINE

The values must be calculated according to the accuracy requirements of the machine manufacturer (check via the PLC interface or in the FS Service display).

### Angular offset LS/FS

If there must be a defined angular offset between the FS and LS, e.g. when synchronous operation is selected, the “zero degree positions” of the FS and LS must be mutually adapted. This can be done with the following machine data:

- MD 34100 REFP_SET_POS
- MD 34080 REFP_MOVE_DIST
- MD 34090 REFP_MOVE_DIST_CORR

**References**: /FB/, R1, “Reference Point Approach”

### Service display for FS

The following values are displayed for the following spindle for start-up in synchronous operation in the “Service Values Axes” display in the “Diagnosis” operating area:

- Actual deviation between setpoints of FS and LS
  
  Display value: Position offset in relation to leading spindle (setpoint)
  (value corresponds to angular offset between FS and LS that can be read with axis variable $AA_COUP_OFFS in the part program)

- Actual deviation between actual values of FS and LS
  
  Display value: Position offset in relation to leading spindle (actual value)
Supplementary Conditions

Availability of “Synchronous spindle” function
This function is an option and available for
- SINUMERIK 840D, SW 2 and higher

Availability of “WAITC” function
This function is available together with synchronous spindle for
- SINUMERIK 840D, SW 3 and higher

Data Descriptions (MD, SD)

4.1 Description of machine data

4.1.1 Channel-specific machine data

<table>

</tbody>
</table>

Significance:
One synchronous spindle pair per NC channel can be defined in a fixed configuration with this machine data.
The machine axis numbers (channel-specific MD: AXCONF_MACHAX_USED) applicable in the NC channel must be entered for the following spindle [n=0] and the leading spindle [n=1].
If a value of “0” is entered, then the coupling is not configured, thus leaving 2 couplings to be configured freely via the NC part program.

</tr>
</tbody>
</table>

Data type: BOOLEAN

**Applies from SW version**: 2.1

**Significance:**

This machine data determines the type of coupling for the fixed coupling configuration defined with machine data COUPLE_AXIS_1[n].

1: Setpoint coupling activated.

With a setpoint coupling, the reference value for the following spindle is calculated from the position setpoint of the leading spindle, allowing the setpoints for the FS and LS to be input simultaneously. This has a particularly positive effect on the spindle synchronization during acceleration and deceleration processes.

A better response to setpoint changes is thus obtained with the setpoint coupling than with the actual-value coupling.

When a setpoint coupling is selected, the following conditions must be fulfilled before synchronous operation is activated:

- The LS must be assigned to the same NC channel as the FS
- The FS and LS must be in position control mode (SPCON)
- The FS and LS must have the same dynamic control response (see Section 2.4.3)

0: Actual-value coupling activated.

With an actual-value coupling, the reference value for the following spindle is calculated from the position actual value of the leading spindle. With this type of coupling, the following drive must be significantly more dynamic than the leading drive, but never vice versa.

The actual-value coupling can be used, for example, in the following applications:

- The LS must be assigned to a different NC channel than the FS
- For leading spindles which are not suitable for position control
- In cases where the dynamic control response of the leading spindle is considerably slower than that of the following spindle.

As soon as the actual-value coupling is active, the IS "Actual-value coupling" for the FS is set to "1".

2: Speed coupling activated.

The speed coupling is internally a setpoint coupling. The requirements placed on FS and LS are lower. A defined position relation between FS and LS cannot be established.

In the following cases, the speed coupling is applied:

- LS and/or FS are not in position control.
- There are no measuring systems.

The coupling type can be altered in the NC part program when the coupling is deactivated by means of language instruction COUPDEF provided that this option is not inhibited in channel-specific MD: COUPLE_IS_WRITE_PROT_1. The parameterized value of channel-specific MD: COUPLING_MODE_1 does not, however, get altered.

**MD irrelevant for ......**

User-defined coupling

<tr>
<td>Changes effective after Power On</td>
<td></td>
<td>Protection level: 2/7</td>
</tr>
<tr>
<td>Data type: BYTE</td>
<td>Applies from SW version: 2.1</td>
<td></td>
</tr>
</tbody>
</table>

#### Significance:
This machine data determines the condition on which a block change must be executed when synchronous mode is activated for the fixed coupling configuration defined in channel-specific machine data COUPLE_AXIS_1[n].

The following options are available:

- **0**: Block change is enabled immediately
- **1**: Block change in response to "Fine synchronism"
- **2**: Block change in response to "Coarse synchronism"
- **3**: Block change in response to IPOSTOP (i.e., after setpoint-based synchronism)

The block change response can be altered in the NC part program with language instructions COUPDEF provided this option has not been inhibited with channel-specific MD: COUPLE_IS_WRITE PROT_1. The parameterized value of channel-specific MD: COUPLE_BLOCK_CHANGE_CTRL_1 does not, however, get altered.

The selected block change response remains valid even when the speed ratio is changed or a defined angular offset is programmed while the coupling is active.

### COUPLE_RESET_MODE_1

<table>
<thead>

<tr>
<td>Data type: BYTE</td>
<td>Applies from SW version: 2.1</td>
<td></td>
</tr>
</tbody>
</table>

#### Significance:
The behavior of synchronism for the synchronous spindle pair configured with the machine data COUPLE_AXIS_n is defined with this machine date.

- **Bit 0=0**: Synchronism remains active with a new program start and can be cancelled only with COUPOF as long as the control remains switched on.
- **Bit 0=1**: Synchronism is cancelled with program start (from the reset condition).
- **Bit 1=0**: Synchronism remains active even with program end and reset and can be cancelled only with COUPOF as long as the control remains switched on.
- **Bit 1=1**: Synchronism is cancelled with program end or RESET.
- **Bit 5=1**: The configured data are activated with program start.
- **Bit 6=1**: The configured data are activated with program end or RESET.
- **Bit 9=1**: Synchronism is switched on with program start.

Note: Synchronism is not deselected with NC start after NC stop!

4.1.2 Axis-specific machine data

37200
MD number

COUPLE_POS_TOL_COARSE
Threshold value for coarse synchronism

Default value: 1.0
Min. input limit: 0.0
Max. input limit: PLUS
Changes effective after NEW_CONF
Protection level: 2/7
Unit: –
Data type: DOUBLE
Applies from SW version: 2.1

Significance:
In synchronous operation, the positional deviation between the leading and following spindles is monitored (only DV and AV mode).

IS “Coarse synchronism” is set if the current positional deviation is within the tolerance band specified by the threshold value.

Furthermore, this threshold value represents the criterion for a block change on activation of synchronous operation or on alteration of the transmission parameters when the coupling is active in cases where “Coarse synchronism” is selected as the block change response condition (see channel-specific MD: COUPLE_BLOCK_CHANGE_CTRL_1 or language instruction COUPDEF).

If the value “0” is input, IS “Coarse synchronism” is always set to “1” in DV and AV mode.

Related to ....
Channel-specific MD: COUPLE_BLOCK_CHANGE_CTRL_1 (block change response in synchronous spindle operation)
IS “Coarse synchronism” (DB31–48, DBX98.1)
### Description of machine data

#### 37210 COUPLE_POS_TOL_FINE

**MD number**: 37210  
**Description**: Threshold value for fine synchronism  
**Default value**: 0.5  
**Min. input limit**: 0.0  
**Max. input limit**: PLUS  
**Changes effective after**: NEW_CONF  
**Protection level**: 2/7  
**Unit**:  
- Linear axis: mm  
- Rotary axis: degrees  
**Data type**: DOUBLE  
**Applies from SW version**: 2.1  
**Significance**:  
In synchronous operation, the positional deviation between the leading and following spindles is monitored (only DV and AV mode).  
IS “Fine synchronism” is set if the current positional deviation is within the tolerance band specified by the threshold value.  
Furthermore, this threshold value represents the criterion for a block change on activation of synchronous operation or on alteration of the transmission parameters when the coupling is active in cases where “Fine synchronism” is selected as the block change response condition (see channel-specific MD: COUPLE_BLOCK_CHANGE_CTRL_1 or language instruction COUPDEF).  
If the value “0” is input, IS “Fine synchronism” is always set to “1” in DV and AV mode.  

**Related to**: Channel-specific MD; COUPLE_BLOCK_CHANGE_CTRL_1 (block change response in synchronous spindle operation)  
IS “Fine synchronism” (DB31–48, DBX98.0)

#### 37220 COUPLE_VELO_TOL_COARSE

**MD number**: 37220  
**Description**: “Coarse” speed tolerance between leading and following spindles  
**Default value**: 1.0  
**Min. input limit**: 0.0  
**Max. input limit**: PLUS  
**Changes effective after**: NEW_CONF  
**Protection level**: 2/7  
**Unit**:  
- Linear axis: mm/min  
- Rotary axis: rpm  
**Data type**: DOUBLE  
**Applies from SW version**: 3.1  
**Significance**:  
In synchronous operation, the speed difference between the leading and following spindles is monitored (VV mode only).  
IS “Coarse synchronism” is set if the current speed difference is within the tolerance band specified by the threshold value.  
Furthermore, this threshold value represents the criterion for a block change on activation of synchronous operation or on alteration of the transmission parameters when the coupling is active in cases where “Coarse synchronism” is selected as the block change response condition (see channel-specific MD: COUPLE_BLOCK_CHANGE_CTRL_1 or language instruction COUPDEF).  
If the value “0” is input, IS “Coarse synchronism” is always set to “1” in VV mode.  

**Related to**: Channel-specific MD; COUPLE_BLOCK_CHANGE_CTRL_1 (block change response in synchronous spindle operation)  
IS “Coarse synchronism” (DB31–48, DBX98.1)

### 4.2 Description of setting data

#### 37230

<table>
<thead>
<tr>
<th><strong>COUPLE_POS_TOL_FINE</strong></th>
<th>“Fine” speed tolerance between leading and following spindles</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default value: 0.5</td>
<td>Min. input limit: 0.0</td>
</tr>
<tr>
<td></td>
<td>Max. input limit: PLUS</td>
</tr>
<tr>
<td>Changes effective after</td>
<td>Protection level: 2/7</td>
</tr>
<tr>
<td>NEW_CONF</td>
<td>Unit: Linear axis: mm/min</td>
</tr>
<tr>
<td></td>
<td>Rotary axis: rpm</td>
</tr>
<tr>
<td>Data type: DOUBLE</td>
<td>Applies from SW version: 3.1</td>
</tr>
</tbody>
</table>

**Significance:**
- In synchronous operation, the speed difference between the leading and following spindles is monitored (VV mode only).
- IS “Fine synchronism” is set if the current speed difference is within the tolerance band specified by the threshold value.
- Furthermore, this threshold value represents the criterion for a block change on activation of synchronous operation or on alteration of the transmission parameters when the coupling is active in cases where “Fine synchronism” is selected as the block change response condition (see channel-specific MD: COUPLE_BLOCK_CHANGE_CTRL_1 or language instruction COUPDEF).
- If the value “0” is input, IS “Fine synchronism” is always set to “1” in VV mode.

**Related to:**
- Channel-specific MD: COUPLE_BLOCK_CHANGE_CTRL_1 (block change response in synchronous spindle operation)
- IS “Fine synchronism” (DB31–48, DBX98.0)

#### 42300

<table>
<thead>
<tr>
<th><strong>COUPLE_RATIO_1[n]</strong></th>
<th>Speed ratio parameters for synchronous spindle mode [n]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default value: 1.0</td>
<td>Min. input limit: –1000</td>
</tr>
<tr>
<td></td>
<td>Max. input limit: 1000</td>
</tr>
<tr>
<td>Changes effective after</td>
<td>Protection level: MMC-MD 9220</td>
</tr>
<tr>
<td>NEW_CONF</td>
<td>Unit: –</td>
</tr>
<tr>
<td>Data type: DOUBLE</td>
<td>Applies from SW version: 2.1</td>
</tr>
</tbody>
</table>

**Significance:**
- This setting data determines the speed ratio parameters for the fixed configuration defined with channel-specific MD: COUPLE_AXIS_1[n].
- The linear correlation between the leading and following spindles is determined by speed ratio $k_0$. This ratio is input by two speed ratio parameters in the form of numerator [n=0] and denominator [n=1], allowing the speed ratio to be specified very exactly.

$$
\frac{k_0 = \frac{\text{Speed ratio parameter nominator}}{\text{Speed ratio parameter denominator}}} = \frac{\text{SSC_COUPLE_RATIO[0]}}{\text{SSC_COUPLE_RATIO[1]}}
$$

- The speed ratio parameters can be altered in the NC part program with language instruction COUPDEF provided that this option is not inhibited with channel-specific COUPLE_IS_WRITE_PROT_1. The parameterized values of SD: SSC_COUPLE_RATIO_1 do not, however, get altered. The calculation of $k_0$ is initiated with POWER ON.

**SD irrelevant for:**
- User-defined coupling

**Related to:**
- SD: SSC_COUPLE_RATIO_1 currently has the same action as a machine data (e.g. active after POWER ON). The SD data are therefore displayed and input in the same way as channel-specific machine data.

- Channel-specific MD: COUPLE_AXIS_1 (definition of synchronous spindle pair)
## Signal Descriptions

### 5.1 Axis/spindle-specific signals

#### 5.1.1 Signals from axis/spindle

<table>
<thead>
<tr>
<th>DB31–48</th>
<th>Synchronous mode</th>
<th>Edge evaluation: no</th>
<th>Signal(s) updated: cyclically</th>
<th>Signal(s) valid from SW vers.: 2.1</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBX84.4</td>
<td>Signal(s) from axis/spindle to PLC (NCK → PLC)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Signal state 1 or signal transition 0 —> 1**

The spindle is operating in "Synchronous operation" mode. The following spindle is therefore following the motions of the leading spindle according to the transmission ratio. The monitoring functions for coarse and fine synchronism are implemented in synchronous operation.

Note: The signal is set only for the machine axis which is acting as following spindle (IS "FS active" = 1)

<table>
<thead>
<tr>

<td>Signal(s) from axis/spindle to PLC (NCK → PLC)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Signal state 0 or signal transition 1 —> 0**

The spindle is not operated as the following spindle in "synchronous mode".

When the coupling is deactivated (deselection of synchronous operation), the following spindle is switched to "open-loop control mode".

</tr>
</thead>
<tbody>
<tr>
<td><strong>DBX98.4</strong></td>
<td><strong>Signal(s) from axis/spindle to PLC (NCK → PLC)</strong></td>
</tr>
<tr>
<td><strong>Signal state 1 or signal transition 0 → 1</strong></td>
<td>The following spindle traverses an additional motional component which is overlaid on the motion from the coupling with the leading spindle.</td>
</tr>
<tr>
<td><strong>Examples of overlaid movement of FS:</strong></td>
<td></td>
</tr>
<tr>
<td>• Activation of synchronous operation with defined angular offset between FS and LS</td>
<td></td>
</tr>
<tr>
<td>• Activation of synchronous operation with LS in rotation</td>
<td></td>
</tr>
<tr>
<td>• Alteration of transmission ratio when synchronous operation is selected</td>
<td></td>
</tr>
<tr>
<td>• Input of a new defined angular offset when synchronous operation is selected</td>
<td></td>
</tr>
<tr>
<td>• Traversal of FS with plus or minus traversing keys or handwheel in JOG when synchronous operation is selected</td>
<td></td>
</tr>
<tr>
<td>As soon as the FS executes an overlaid movement, IS “Fine synchronism” or IS “Coarse synchronism” (depending on threshold value) may be cancelled immediately.</td>
<td></td>
</tr>
<tr>
<td><strong>Note:</strong> The signal is relevant only for the following spindle in synchronous operation.</td>
<td></td>
</tr>
<tr>
<td><strong>Signal state 0 or signal transition 1 → 0</strong></td>
<td>The following spindle does not traverse any additional motional component or this motion has been terminated.</td>
</tr>
<tr>
<td><strong>Related to....</strong></td>
<td>IS &quot;Synchronous operation&quot; (DB31–48, DBX84.4)</td>
</tr>
</tbody>
</table>
### 5.1 Axis/spindle-specific signals

#### DB31–48 DBX99.0

**LS (leading spindle) active**

<table>
<thead>
<tr>
<th>Signal(s) from axis/spindle to PLC (NCK → PLC)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Edge evaluation: no</td>
</tr>
<tr>
<td>Signal(s) updated: cyclically</td>
</tr>
<tr>
<td>Signal(s) valid from SW vers.: 2.1</td>
</tr>
</tbody>
</table>

- **Signal state 1 or signal transition 0 —> 1**: The machine axis is currently active as the leading spindle. 
  - Note: The signal is relevant only in synchronous operation.

- **Signal state 0 or signal transition 1 —> 0**: The machine axis is not currently active as the leading spindle.

**Related to ....**

- In the case of faults/disturbances on the following spindle which result in cancellation of the FS "servo enable", the coupling relationship between the FS and LS is reversed and switched over to an actual-value coupling internally in the control under certain circumstances.
  - In this case, the leading spindle becomes the new, active following spindle (IS "FS active").

**Related to ....**

- IS "Synchronous operation" (DB31–48, DBX84.4)
  - IS "FS active" (DB31–48, DBX99.1)

---

#### DB31–48 DBX99.1

**FS (following spindle) active**

<table>
<thead>
<tr>
<th>Signal(s) from axis/spindle to PLC (NCK → PLC)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Edge evaluation: no</td>
</tr>
<tr>
<td>Signal(s) updated: cyclically</td>
</tr>
<tr>
<td>Signal(s) valid from SW vers.: 2.1</td>
</tr>
</tbody>
</table>

- **Signal state 1 or signal transition 0 —> 1**: The machine axis is currently operating as the following spindle. 
  - The following spindle thus follows the movements of the leading spindle in synchronous operation in accordance with the transmission ratio. 
  - Note: The signal is relevant only in synchronous operation.

- **Signal state 0 or signal transition 1 —> 0**: The machine axis is not currently operating as the following spindle.

**Related to ....**

- In the case of faults/disturbances on the following spindle which result in cancellation of the FS "servo enable", the coupling relationship between the FS and LS is reversed and switched over to an actual-value coupling internally in the control under certain circumstances.

**Related to ....**

- IS "Synchronous operation" (DB31–48, DBX84.4)
  - IS "LS active" (DB31–48, DBX99.0)

Brief Description

**Auxiliary function output to PLC**

For software version 4 and higher, a description of the auxiliary functions is contained in `/FB/ H2, Auxiliary Function Output to PLC`

**Motion-synchronous actions**

With the support of motion-synchronous actions, it is possible to execute programmed actions in synchronism with the block and/or along the programmed path as a function of programmed conditions.

The following are some of the possible actions:

- Output of M and H auxiliary functions to the PLC
- Output of digital and analog signals
- Execution of NC commands parallel to machining (e.g. delete distance-to-go)
- Switchover between several feedrates in a programmed block as a function of binary and/or analog signals
- Start of evaluation function (e.g. for AC control)
- Feedrate overrides
- Axial motion overlays
  this enables e.g. to implement a distance control for laser processing.

These actions can be started as a function of parameterized conditions such as:

- Status of a digital or analog input
- Status of a digital or analog output
- Actual position of an axis
- Time from block start
- Distance from block start
- Distance to block end

With SW version 3.2 and higher, it is possible to form the condition by comparison of the status sizes in the IPO cycle.

Example:
Comparison of the actual value of an axis with the setting data for the reversal oscillation position. Any changes to the setting data are effective at once.
Detailed Description

2.1 Auxiliary function output to PLC

For SW 4 and higher, a description of the signals of the auxiliary functions is provided in /FB/ H2, Auxiliary Function Output to PLC.
2.2 Motion-synchronous actions (up to and including SW 3)

2.2.1 General motion-synchronous actions

Application

Reaction to events/states during execution of a motion block.

Motion-synchronous actions allow the user to initiate actions in synchronism with machining operations. The instant of activation of these actions can be defined by a condition which means that actions of this type do not need to be started in connection with block limits.

These synchronous actions are performed in the IPO cycle.

Examples of typical motion-synchronous actions are:

- **Transfer of M and H auxiliary functions to the PLC**
  The auxiliary functions programmed in an NC block are transferred to the PLC as a function of a relational operation or an external signal.

- **Axis-specific deletion of distance-to-go**
  For example, high-speed inputs effect a conditional stop and deletion of distance-to-go with respect to path or positioning axes.

- **Programmed read-in disable**
  The read-in disable can be set or cancelled in the part program as a function of, for example, an external input.

Schematic

![Schematic of motion-synchronous actions](image)

Fig. 2-1 Motion-synchronous actions
Functionality and syntax

A motion-synchronous action consists of a condition, up to 16 associated synchronous commands and, in some cases, an identification number.

The schematic of motion-synchronous actions is as follows:

```
| ID no. | Keyword: WHEN | WHENEVER | FROM | Condition | DO | Actions |
```

- Numbers 1...16 with modal-synchronous actions, does not apply with non-modal actions.
- Evaluation duration of the condition

**Example:** Activate cooling agent 10 mm before end of block

```
WHEN $AC_DTEW<=10 DO M8
```

Fig. 2-2 Structure of motion-synchronous actions

---

**Note**

A motion-synchronous action is positioned on its own in a block and acts in the next block with a machine function (e.g. block with G01, G02, G04, auxiliary function output).

The instruction can act modally or non-modally.

A total maximum of 16 modal and non-modal motion-synchronous actions can be operative in a machining block.

Several actions can be specified for a condition, e.g. ...

`DO M8 M800`

A motion-synchronous action is terminated with the end of the output block unless it is identified by means of an identification number ('ID='<number>;) as having a modal action. Identification numbers from 1 to 16 may be used in each channel.

Motion-synchronous actions are processed in order of their ID numbers (i.e. block with ID number 1 before block with ID number 2...). After processing of the modal motion-synchronous actions, the non-modal actions are processed in the order in which they were programmed.

---

**Note**

If a variable is written several times by motion-synchronous actions, then the last value to be written is valid.

Modal motion-synchronous actions can be terminated with the 'CANCEL('expression>{1,16} ') command.

The system variable $PC_ACTID[<1, 16>] can be used to read whether an ID number is currently active.
Depending on the keyword programmed in the synchronized action instruction, the function responds as follows:

Table 2-1  Keywords for synchronized action instructions

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>'WHEN'...'DO'...</td>
<td>A condition is evaluated continuously until it is fulfilled once. The synchronous commands programmed after 'DO' are then executed once.</td>
</tr>
<tr>
<td>'WHenever'...'DO'...</td>
<td>The synchronous commands are executed cyclically for as long as the condition is fulfilled.</td>
</tr>
<tr>
<td>'FROM'...'DO'...</td>
<td>The synchronous commands are executed cyclically if the condition is fulfilled once.</td>
</tr>
<tr>
<td>...'DO'...</td>
<td>In the absence of 'WHEN', 'WHenever' or 'FROM', the condition is regarded as being permanently fulfilled and the synchronous commands are executed cyclically.</td>
</tr>
</tbody>
</table>

**Conditions**

The condition is the comparison of a real-time variable with a value calculated at the time of block preparation:

WHEN $AA_IM[Y] > 10 * SIN(R10) DO ... 

or the comparison of two real-time variables:

WHEN $AC_VACTW > $$A_INA[1] DO ...

In this case, the real time variable must be marked on the right with $S$ as real-time variable.

The form of the conditions which may be used in motion-synchronous actions is as follows:

<read real-time variable><relational operator><$S$read real-time variable> <read real-time variable><relational operator><expression>

**Note**

The data types BOOL, CHAR, INTEGER and REAL are admissible in the condition. The comparison is made on the left of the data type of the real-time variable. The type conversion rules for value allocation apply. If two real-time variables are compared, these must have the same data type.

A block change to the following block without fulfillment of the specified conditions results in the following response:

- Non-modal motion-synchronous actions are made inoperative
- Modal motion-synchronous actions remain operative

All motion-synchronous actions are deleted by a reset.
Priorities when several motion-synchronous actions are programmed

  :
  :
  :

Since the modal motion-synchronous actions are processed in ascending order of their ID numbers and the non-modal actions have priority, analog output 3 is set to a value of 7 and output 4 to a value of 30 in the next block with a machine function if inputs 1, 3, 5 and 7 are simultaneously set.

With SW 3.2 and higher, it is possible to compare the synchronization conditions in the IPO cycle with real-time variable with the current actual values ($$ variable on the right or left of comparison conditions). With normal system variable comparison, the expressions are evaluated in the first run.

With comparison of the $$ real-time variable, the change of the reversal position during oscillation may become effective during oscillation in synchronization.

References: /FB/, P5 “Oscillation”

Example 1
On the left-hand side of the comparison, there is a variable evaluated in real time while, on the right-hand side any random expression is shown and not any of the permitted real-time processing variables that start with $$.

M120 is output during the movement programmed in the following block if the actual value of the X axis is greater than the value of analog input 1. The actual value is reevaluated in each IPO cycle while the value of the analog input is formed at the time of interpretation.

The comparison is initiated in real time.

Example 2
On the left-hand side there is a comparison variable evaluated in real time and on the right-hand side of the comparison a real-time variable permitted for the synchronized action that begins with $$.

Comparison of the current actual value of the X axis in IPO cycles with the analog input 1 because a $$ variable is on the right-hand side of the comparison.

The two variables are compared in IPO cycles.

Example 3
$$ variables are permissible on the left-hand side of the comparison.

Identical to example 2. The left-hand and right-hand sides are always compared in real time.
Real-time variables

As a condition, the following real-time variables can be read, their status scanned and a comparison made between them and another value:

DO $AC_MARKER[0]=2 &lt;br&gt;WHEN ... DO $AC_MARKER[0]=3 &lt;br&gt;WHEN $AC_MARKER[0]==3 DO $AC_OVR=50 &lt;br&gt;The parameters can be read and overwritten in the part program even independently of synchronized actions: &lt;br&gt;IF$AC_MARKER[0] == 4 GOTOF SPRUNG</td>
<td>INTEGER</td>
</tr>
</tbody>
</table>
### 2.2 Motion-synchronous actions (up to and including SW 3)

#### Table 2-2 Read real-time variable

<table>
<thead>
<tr>
<th>Real-time variable</th>
<th>Meaning</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\text{AC_PARAM}[&lt;\text{arith. expression}&gt;]$</td>
<td>Floating point parameter for synchronized actions. Serves for buffering and evaluating synchronized actions. There are 50 parameters (index 0...49). Example: WHEN $\text{A_IN}[3]==1$ DO $\text{AC_PARAM}[49] = $$\text{AA_IM}[X]$) WHENEVER $\text{AC_PARAM}[1]\geq$$\text{AC_PARAM}[49]$ DO ... FCTDEF(1,–1000,1000,0,1,–2) DO SYNFCT(1,$\text{AC_OVR}$, $\text{AC_PARAM}[49]$)</td>
<td>REAL</td>
</tr>
</tbody>
</table>

If input 3 is applied, the actual value of the X axis is stored in parameter 0.

The parameters can also be read and written in the part program independently of synchronized actions.

#### Note

Details about the resolution and rated range of the analog input and output modules used can be found in:

**References:**
- /PHF/, SINUMERIK FM-NC, NCU 570 Manual
- /S7H/, SIMATIC S7, Manual

The distance from the block start or to the block end on paths is always the distance between the point on the center path of the tool and the programmed start or end point.

Contrary to this, the path distance from block start/block end is indicated via $\text{AC\_PLTBB}$ and $\text{AC\_PLTEB}$.

#### Example

Activation of auxiliary function before end of block

WHEN $\text{AC\_DTEW}\leq10$ DO M8

Activation of cooling agent 10 mm before end of block.

![Fig. 2-3 Calculation of distance for path conditions](image)
The following synchronous commands can be programmed as the reaction to a fulfilled condition:

- Write data to real-time variable
- Output of M and H auxiliary functions to the PLC
- Activation of synchronous procedures
- Activation of evaluation functions

\[
\text{< write_real_time_variable > } \text{'=' } \text{< read_real_time_variable >} \\
\text{< write_real_time_variable > } \text{'=' } \text{< expression >} \\
\text{< auxiliary function >} \\
\text{< synchronous_procedure >} \\
\text{< evaluation_function >}
\]

If there is a $\text{S}$ real-time variable admissible for the synchronized action on the right of the allocation, the value is formed currently in the IPO cycle.

Example:

\[
\text{DO } \text{SSA.OUT[1]} = \text{SSAA.IB[Z]} \text{ ; The actual value is set to the output in the IPO cycle.}
\]

If there is an arbitrary expression on the right, the value is formed for block preparation. Variables with $\text{S}$ or $\text{SS}$ are admissible on the left side.

### Write real-time variable

A value or status can be assigned to one of the following real-time variables as a synchronous command:

<table>
<thead>
<tr>
<th>Real-time variable</th>
<th>Meaning</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\text{A.OUT[&lt;arith. expression&gt;] }$</td>
<td>Digital output</td>
<td>BOOL</td>
</tr>
<tr>
<td>$\text{A.OUTA[&lt;arith. expression&gt;] }$</td>
<td>Analog output (see under &quot;Constant analog value output&quot; in Section 3) Unit: A value of 1000 corresponds to 1 V.</td>
<td>REAL</td>
</tr>
<tr>
<td>$\text{AC_MARKER[&lt;arith. expression&gt;] }$</td>
<td>Marker variable: Can be used in synchronized actions for the generation of complex conditions. There are 8 markers (index 0 ... 7). With reset, the markers are set to 0. Example: WHEN ... DO $\text{AC_MARKER[0]}=2$ WHEN ... DO $\text{AC_MARKER[0]}=3$ WHEN $\text{AC_MARKER[0]}==3$ DO $\text{AC_OVR}=50$</td>
<td>INTEGRER</td>
</tr>
<tr>
<td>$\text{AC_VC }$</td>
<td>Additive path feedrate override</td>
<td>REAL</td>
</tr>
<tr>
<td>$\text{AAA_VC[&lt;axial expression&gt;] }$</td>
<td>Additive axis feedrate override (applies only to positioning axes). The effective feedrate override is calculated as follows: [ \text{Feff} = \text{Fprog} + \text{Fover} \text{ or } \text{FA[X]} = \text{FA[X]}<em>{\text{prog}} + \text{FA[X]}</em>{\text{over}} \text{. The additional feed offset is interpreted in the current feed unit (e.g. mm/min, degree/min).} \text{ The additive path feedrate override is not effective with G0, G33, G331, G332 and G63. When override = 0, the value entered in the real-time variable is not effective; otherwise the override has no effect on the override value. The total feedrate cannot become negative as a result of the override value. An upper limit is imposed to ensure that the maximum axis speeds and acceleration rates and the path velocities stipulated by the Look Ahead are not exceeded.}</td>
<td>REAL</td>
</tr>
</tbody>
</table>
### 2.2 Motion-synchronous actions (up to and including SW 3)

#### Table 2-3 Write real-time variable

<table>
<thead>
<tr>
<th>Real-time variable</th>
<th>Meaning</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>$AC_OVR</td>
<td>Path override factor for synchronized actions.</td>
<td>REAL</td>
</tr>
<tr>
<td>$AA_OVR[&lt;axial expression&gt;]</td>
<td>Axial override factor for synchronized actions (applies only to positioning axes). Multiplicative override component which acts in addition to the programmed override factors or to those specified by handwheel or via PLC interface. The effective total factor is limited to 200%. The multiplicative override component must be rewritten in every IPO cycle, otherwise a value of 100% is applied. $AA_OVR[S1] is used to modify the spindle speed override. The override values defined in machine data MD: $MN_OVR_FACTOR_LIMIT_BN, MD: $MN_OVR_FACTOR_FEEDRATE[30], MD: $MN_OVR_FACTOR_AX_SPEED[30], MD: $MN_OVR_FACTOR_SPIND_SPEED must not be exceeded with additive feedrate override. The additive feedrate override is limited in such a way that the resulting feedrate does not exceed the maximum override value of the original feedrate.</td>
<td>REAL</td>
</tr>
<tr>
<td>$AA_OFF</td>
<td>Overlaid movement for the programmed axis. The offset is traversed immediately independently of whether the axis is programmed or not. In this way, a distance control can be implemented. The type of calculation is defined via the axial MD: $MA_AA_OFF_MODE (proportional or integrating). The speed of the overlaid movement is limited by axial MD: $MA_CORR_VEL. The offset is reset on Reset. No axial movement is performed. The current position is resynchronized. The current offset is not displayed separately. It is indicated by the difference between the MCS and the WCS in the actual value display.</td>
<td>REAL</td>
</tr>
<tr>
<td>$AC_PARAM[&lt;arith. expression&gt;]</td>
<td>Floating point parameter for synchronized actions. Used to buffer and evaluate synchronized actions. 50 parameters (index 0...49) are available. Example: WHEN $A_IN[3]==1 DO $AC_PARAM[0] = $$AA_IM[x] If input 3 is set the actual value of the X axis in parameter 0 is stored. The parameters can also be read and written in the part program independently of synchronized actions.</td>
<td>REAL</td>
</tr>
</tbody>
</table>

**Example 1**

Set a digital output

If the actual value of axis Q1 exceeds 10mm (assuming that the metric measuring system is selected), set output 3.

**Example 2**

Analog output

If digital output 3 is set, output a 0.7 V voltage at output 5 (assuming value of 1000 corresponds to 1 V).
Output of auxiliary functions to PLC

An M or H auxiliary function can be output to the PLC as a synchronous command.

A total of 10 M or H auxiliary functions in a machining block can be output as synchronous commands.

The auxiliary functions are output to the PLC if the associated conditions are fulfilled. The output time specified in MD: AUXFU_GROUP_SPEC (auxiliary function group specification) or AUXFU_[M, H]_SYNC_TYPE (instant of output of [M, H] functions) are not effective.

The PLC acknowledges an auxiliary function either after a complete PLC user cycle or immediately depending on whether it is defined as a normal or as a high-speed auxiliary function.

The block change is not affected by the acknowledgment.

An auxiliary function may only be output once to the PLC, i.e. it may only be programmed with keyword "WHEN" and with a non-modal action.

M functions in groups 1 to 6 and M6 or the M functions for tool change set via MD may not be output as motion-synchronous actions.

Example

Several auxiliary functions in block

WHEN $AA_IW[Q1]>5 DO M172 H510

If the actual value of axis Q1 exceeds 5 mm, output auxiliary functions M172 and H510 to the PLC interface.

Synchronous procedure

One of the following synchronous procedures can be activated as a synchronous command.

Table 2-4 Synchronous procedures

<table>
<thead>
<tr>
<th>Synchronous procedure</th>
<th>Meaning</th>
</tr>
</thead>
</table>
| ‘RDISABLE’            | Programmed read-in disable:  
If a block is processed after a synchronized action was activated with action RDISABLE, then further processing of the block is stopped if the associated condition is fulfilled. Only the programmed motion-synchronous actions are processed. RDISABLE means interruption of continuous-path operation, even if the read-in disable is not active.  
If the condition for the RDISABLE instruction is not longer fulfilled, the read-in disable is cancelled. Examples are shown below.  
**Application:** This procedure allows, for example, the program to be started in the IPO cycle as a function of external inputs. |

| ‘STOPREOF’           | Acknowledgment of preprocessing stop:  
A motion-synchronous action with a STOPREOF command stops block preparation after the next machining block. The stop is cancelled again at the end of the machining block or if the condition for the STOPREOF command is fulfilled.  
STOPREOF may only be programmed with keyword "WHEN" and as a non-modal command.  
**Application:** Rapid program branching at block end. |
### 2.2 Motion-synchronous actions (up to and including SW 3)

#### Table 2-4 Synchronous procedures

<table>
<thead>
<tr>
<th>Synchronous procedure</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>'DELDTG[&lt;axial expression&gt;]'</td>
<td>Delete distance-to-go for path axes</td>
</tr>
<tr>
<td>'DELDTG[&lt;axial expression&gt;]'</td>
<td>A motion-synchronous action with a DELDTG command effects a preprocessing stop after the next block with machine function. If the condition for the DELDTG command is fulfilled, delete distance-to-go is implemented and the preprocessing stop is cancelled. The preprocessing stop is also cancelled at the end of the block with machine function. No continuous-path mode or overgrinding is possible in a block for which DELDTG applies. Continuation of the following block is faster if G603: &quot;Block change with IPO end&quot; is active. The distance to the programmed target point (in WCS) is entered in system variable $AC_DELT if the path distance-to-go has been deleted. The axial distance to the target point for axial deletion of distance-to-go is stored in system variable $AA_DELT[&lt;axis&gt;]. 'DELDTG' and 'DELDTG[&lt;axial expression&gt;] may only be programmed with keyword 'WHEN' and as a non-modal command. Application: Deletion of distance-to-go for path or positioning axes.</td>
</tr>
</tbody>
</table>

**Example 1**

Programmed read-in disable

a)  
N10  WHEN $A\_IN[1] == 0 DO RDISABLE  
N15  G01 X10 F1000  
N20  Y20  
...  
If input 1 at the end of N15 has value 0, then changing N20 is delayed until the input has value 1. During the blocking, exact stop is triggered between N15 and N20. Application: RDISABLE can be used if the continuation of processing at a part program location depends on reception of an enabling signal. The example can be used so that processing is only continued in N20 when an enabling signal from the PLC is present. (For example, another axis has left the working space or the door to the automatic tool changer is open).

b)  
WHENEVER $A\_INA[2]<7000 DO RDISABLE  
If the voltage at input 2 drops below 7 V, program processing is stopped (assuming value of 1000 corresponds to 1 V).
Example 2
Program branching
WHEN $AC\_DTEB<5$ DO STOPREOF
G01 X100
IF $A\_INA[7]>5000$ GOTO Label 1
If the distance to the block end is less than 5 mm, terminate preprocessing stop. If the voltage exceeds 5 V at input 7, jump forward to label 1 (assuming value of 1000 corresponds to 1 V).

Example 3
Axis-specific deletion of distance-to-go
WHEN $A\_INA[5]>8000$ DO DELDTG(X1)
If the voltage exceeds 8 V at input 5, delete the distance-to-go of axis X1 (assuming value of 1000 corresponds to 1 V).
An evaluation function (SYNFCT) can be activated as a synchronous command.

With an evaluation function, it is possible – in synchronism with a machining operation – to read a variable, evaluate it with a polynomial function and write the result to another variable.

This function can be used, for example, to influence the feedrate of an axis as a function of a measured loop current.

An evaluation function has the following syntax:

`SYNFCT('arithmetic expression, <write_real-time variable>, <read_real-time variable>')`

The first parameter selects one of three evaluation functions defined by the user in the channel.

An evaluation function consists of a 3rd order polynomial and is determined in each case by 4 polynomial coefficients $AC_FCTxxC[0,...,3]$, $(xx = \text{number of function: 1, 2 or 3})$.

Polynomial: $y = a_3x^3 + a_2x^2 + a_1x + a_0$

Polynomial coefficients:
- $a_3$: $AC_FCTxxC[3]$
- $a_2$: $AC_FCTxxC[2]$
- $a_1$: $AC_FCTxxC[1]$
- $a_0$: $AC_FCTxxC[0]$

The function value can be limited downwards by means of system variable $AC_FCTxxLL$ and upwards with $AC_FCTxxUL$ $(xx = 1, 2, 3)$.

Programmed polynomial coefficients and limits for the function value take immediate effect.

All REAL real-time variables listed under “Synchronous commands” may be specified for `<write_real-time variable>` and all REAL real-time variables listed under “Conditions” may be specified for `<read_real-time variable>`.

The operating principle of the ‘SYNFCT’ evaluation function is as follows:
- The polynomial defined by the arithmetic expression is evaluated with the value of “read_real-time variable”. Upper and lower limits are then applied to the result which is then assigned to “write_real-time variable”.

The form of the synchronous commands which may be used in motion-synchronous actions is as follows:

With the command

`FCTDEF(‘<polynomial no.>, <lower_Limit>, <upper_Limit>, <Coeff0>, <Coeff1>, <Coeff2>, <Coeff3> ’)`

it is possible program the limits and polynomial coefficients of the evaluation functions to be synchronized with machining operations.

The first parameter selects the evaluation function, the next two parameters define the upper and lower limits of the function values and the next four ones determine the polynomial coefficients.

The command for the above example is thus as follows:

`FCTDEF(1,0,100,0,0.8,0,0)`
`ID=1 DO SYNFCT(1,$AA_VC[U1], $A_INA[2])`
2.2 Motion-synchronous actions (up to and including SW 3)

Example 1

The first evaluation function must be defined with limits 0 and 100 [mm/min] and pitch 0.8.
The 0.8 \( \times \) value of analog input 2 must then be added to the velocity of axis U1 using the evaluation function.

⇒ Evaluation function: \( \$AA_{VC}[U1] = 0.8 \times \$A_{INA}[2] \)

Fig. 2-5 Example of an evaluation function

⇒ Part program:

\[
\begin{align*}
\$AC\_FCT1C[3] &= 0 \\
\$AC\_FCT1C[2] &= 0 \\
\$AC\_FCT1C[1] &= 0.8 \\
\$AC\_FCT1C[0] &= 0 \\
\$AC\_FCT1LL &= 0 \\
\$AC\_FCT1UL &= 100 \\
ID &= 1 \text{ DO} \ SYNFCT(1, \$AA\_VC[U1], \$A\_INA[2]) \\
G01 \ X100 \ Y200
\end{align*}
\]
Example 2

The change parameter must be controlled as a function of a value requested according to a polynomial of the 3rd order. The override must be reduced from 100 to 1% during the movement.

![Graph showing Override and Path parameter relationship](image)

**Fig. 2-6** Control velocity continuously

⇒ Part program:

```plaintext
FCTDEF(2, 1, 100, 100, –100, –100)
DO SYNFCT(2, $AC_OVR, $AC_PATHN)
G01 X100 Y100 F1000
```

**Online override**

In the case of grinding applications, machining of the workpiece and dressing of the grinding wheel can be executed either in the same channel or in different channels (machining and dressing channels).

![Diagram showing Dressing during machining with a dressing roller](image)

**Fig. 2-7** Dressing during machining with a dressing roller

**References:** /FB/, W4 “Grinding”

With SW 3.2 and higher, online offset FTOC can be activated as synchronous command.

The online offset enables an overlaid movement for a geometry axis according to a polynomial programmed with FCTDEF as a function of a reference value which can be e.g. the actual value of an axis.
The online offset has the following syntax:

```
'FTOC(' polynomial no.,
<read real main variable>, ;Reference value
<len 1_2_3>{,
<channel number>}?,
<spindle number>?')
```

- **Polynomial no.**: Number of the function parameterized before.
- **Read real main variable**: All main variables of type REAL listed with
  "Conditions" are admissible.
- **Length 1_2_3**: Wear parameter to which the offset value
  is added.
- **Channel number**: Target channel in which the offset shall be
  effective. CD dressing is thus possible from a
  parallel channel. If the channel number is
  discarded, the offset is effective in the active
  channel. Online offset with FTOCON must be
  switched on in the target channel of the offset.
- **Spindle number**: This is programmed if a grinding wheel which is not
  active shall be dressed. Prerequisite for this is that
  "constant wheel circumference speed" or "tool
  monitoring" is active. If no spindle number is
  programmed, the active tool is offset.

**Example**

Correct the length of an active grinding wheel

```
%_N_ABRICHT_MPF
FCTDEF(1,-1000,1000,-$AA_IW[V],1)
ID=1 DO FTOC(1,$AA_IW[V],3,1) ; Select online tool offset
 ; derived from V axis movement
 ; length 3 of the active
 ; grinding wheel is corrected in channel 1
WAITM (1,1,2)
G1 V=-0.05 F0.01, G91
G1 V=.... ; Synchronization with machining channel
... CANCEL(1) ; Deselect online offset
...```

**Overlaid movement**

System variable $AA_OFF allows an overlaid movement to be programmed for
each axis in the channel irrespective of the current tool and machining plane.
The shift is retracted immediately independently of whether the axis is
programmed or not. Distance control can thus be implemented.

- **Axial MD**: $AA_OFF_MODE defines the mode of distance calculation.
  - 0: Proportional calculation
  - 1: Integrative calculation

$AC_VACTB and $AC_VACTW as input variables for synchronized actions and
the output are disabled by means of option bits ("Feed-dependent analog-value
control" ⇒ laser power control)!

$AA_OFF, position offset as output variable for synchronized actions for
distance control is disabled via option bit!

Velocity limitation with MD: $MA_CORR_VELO.
Example 1

Distance control

The distance value is calculated on an integrative basis via MD:

\[ \text{AA\_OFF\_MODE}[V]=1 \]

This is effective in the basic system of coordinates, that means before transformation. It can thus be used as distance control in the orientation direction (after frame selection with TOFRAME).

The programmed conditions for the current motion-synchronous actions are acquired in the IPO cycle until they are fulfilled or until the end of the following block with machine function is reached.

With SW 3.2 and higher, a comparison of the synchronization conditions is made in the IPO cycle in the main run with introduction of a $$ main variable approved for synchronized actions.

Note

Whether or not frames are included in the calculation depends on which coordinate system (BCS or WCS) a real-time variable is defined in.

Distances are always calculated in the selected basic system (metric or inches). A switchover with G70 or G71 has no effect.

DRF offsets, external zero point offsets, etc. are only taken into account for real-time variables which are defined in the MCS.
2.2 Motion-synchronous actions (up to and including SW 3)

Supplementary conditions

- **Interrupt routines/asyncronous subprograms**
  With activation of an interrupt routine, modal motion-synchronous actions are maintained and are also effective in the asynchronous subprogram. If the subprogram reset is not made with REPOS, the modal-synchronous actions changed in the asynchronous subprogram are effective in the main program.

- **REPOS**
  In the residual block, the synchronized actions are effective as compared to the interruption block. Any modifications on the modal-synchronous actions in the asynchronous subprogram are not effective in the interrupted program. The polynomial coefficients programmed with FCTDEF are not influenced by ASUP and REPOS.

  In the asynchronous subprogram, the coefficients from the program calling up remain effective. In the program calling up, the coefficients from the asynchronous subprogram remain effective.

- **End of program**
  The polynomial coefficients programmed with FCTDET remain effective after the end of program.

- **Block search run**
  In the case of block search run with calculation, they are collected, that means written into the setting data.
2.2.2 Multiple feedrates in a block

Functionality

Using the function “Multiple feedrates in a block” (see Chapter 3), it is possible to activate 6 different feedrate values in one NC block, a dwell and a retraction in synchronism with a movement as a function of external digital and/or analog inputs. The retraction process is initiated on the basis of a predefined value within an IPO cycle. The remaining distance-to-go is deleted.

The HW input signals are combined to form an input byte for the “Multiple feedrates in a block” function. There is a fixed, functional assignment within the byte:

Table 2-5 Input byte for “Multiple feedrates in a block”

<table>
<thead>
<tr>
<th>Bit 7</th>
<th>Bit 6</th>
<th>Bit 5</th>
<th>Bit 4</th>
<th>Bit 3</th>
<th>Bit 2</th>
<th>Bit 1</th>
<th>Bit 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>E7</td>
<td>E6</td>
<td>E5</td>
<td>E4</td>
<td>E3</td>
<td>E2</td>
<td>E1</td>
<td>E0</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Feed address</th>
<th>F7</th>
<th>F6</th>
<th>F5</th>
<th>F4</th>
<th>F3</th>
<th>F2</th>
<th>ST</th>
<th>SR</th>
</tr>
</thead>
</table>

E7 to E2 Activation of feedrates F7 to F2
E1 Activation of dwell ST (in seconds)
E0 Activation of retraction movement SR

The signals are interrogated in ascending order, starting with E0. The retraction movement (SR) therefore has the highest priority and feedrate F7 the lowest.

SR and ST terminate the feed movements with F2–F7. SR also terminates ST, e.g. the complete function.

The higher the bit number, the lower the priority of the signals for feedrates F2–F7. The highest-priority signal determines the current feedrate. MD: MULTIFEED_STORE_MASK (store input signals of “Multiple feedrates in a block” function) can be set to define the response to drop-out of the highest-priority input (F2–F7) in each case.

The block end criterion is fulfilled:

- When the programmed end position is reached
- The retraction movement (SR) has been executed
- The dwell (ST) has expired.

A retraction movement or a dwell leads to deletion of the distance-to-go.

Hardware assignments

Channel-specific MD: MULTFEED_ASSIGN_FASTIN (assignment of input bytes of NC I/Os for “Multiple feedrates in a block” function) can be set to assign a maximum of two digital input bytes or comparator input bytes from the NCK I/O devices to the above input byte.

The input bits can also be inverted with MD: MULTFEED_ASSIGN_FASTIN.

If a 2nd byte is entered, the contents of the 1st and 2 bytes are ORed prior to use.
2.2  Motion-synchronous actions (up to and including SW 3)

The routing of the digital input bytes and parameter assignments of the comparators are described in

References: /FB/, A2 “Various Interface Signals”

**Programming of path movement**

The path feed that remains valid while no input signal is applied is programmed in address F. This feedrate setting is modal.

With F2=... to F7=..., it is possible to program 6 further feedrates in the block in addition to the path feedrate.

The numeric extension specifies the bit number of the input which must change state for the feedrate to become effective.

e.g. F7=1000; 7 means input bit 7

Bits 2 to 7 may be specified as the numeric extension of the feedrate. The programmed values have a non-modal action, i.e. in the following block, the path feedrate programmed under F becomes effective again.

Sparking-out time and retraction path are programmed under additional addresses in the block:

ST=...  Sparking-out time
SR=...  Retraction path

These addresses are effective on a non-modal basis.

**Programming of axial movement**

Axial feedrates that remain valid as long as no input signal is applied are programmed in address FA. They are modally effective.
With FMA[2,x]=... to FMA[7,x]=..., up to 6 further feedrates per axis can be programmed in the block.

The first expression in square brackets indicates the bit number of the input which must change state for the feedrate to become effective. The second expression specifies the axis to which the feedrate applies.

\[ \text{e.g. FMA}[3,Y]=1000; \]

Axial feedrate for Y axis,

3 means input bit 3

Bits 2 to 7 may be specified as the numerical extension of the axial feedrate. The values programmed under FMA are effective on a non-modal basis, i.e. the feedrate programmed under FA becomes effective again in the following block.

Sparking-out time and retraction path can be specified additionally for individual axes:

\[ \text{STA}[x]=... \]

Sparking-out time, axis-specific

\[ \text{SRA}[x]=... \]

Retraction path, axis-specific

The expression in square brackets indicates the axis to which the sparking-out time and retraction path apply.

\[ \text{STA}[X]=2.5; \quad \text{Sparking-out time is 2.5 seconds} \]

\[ \text{SRA}[X]=3.5; \quad \text{Retraction path is 3.5 (unit e.g.: mm)} \]

These addresses are effective on a non-modal basis.

If feedrates, sparking-out time or retraction path are programmed for an axis on the basis of an external input, this axis may not be programmed as a POSA (positioning axis beyond block limit) in this block.

If the input for sparking-out time or retraction path is activated, the distance-to-go for path axes or for the individual axes concerned is deleted and the dwell or retraction operation started.

---

**Note**

The unit for the retraction path refers to the currently selected dimension system (mm or inches).

The status of an input can also be interrogated for synchronous commands of different axes.

Look Ahead is effective even when multiple feedrates are programmed in a block. The currently valid feedrate can thus be limited by the Look Ahead function.

---

**Application**

Examples of typical applications are:

- Analog or digital calipers
  Various feedrate values, a dwell and a retraction path can be activated as a function of external analog or digital inputs. In this case, threshold values are specified via setting data.
- Switchover from infeed to working feedrate via proximity switch
Internal grinding of a ball-bearing ring. The actual diameter is measured by means of calipers and the appropriate feedrate value for roughing, finishing or fine finishing activated in each case as a function of threshold values. The calipers position also supplies the end position. The block end criterion is therefore not only determined by the programmed axis position of the infeed axis, but also by the caliper.

![Diagram of grinding with calipers](image)

**Part program**

```
G00 X40 F=1000;
G01 X48 F=20 F7=5 F3=2.5 F2=0.5 ST=1.5 SR=-0.5
```

**Note**

The axial feedrate or tool feedrate (F value) is the 100% feed. With "Multiple feedrates" in one block (F2 to F7 values), feedrates can be made available that are less than or equal to the axial feedrate or tool feedrate.
2.2.3 AC control (adaptive control)

**General**

The “AC control” function (for Adaptive Control, see Section 3) is used to control one particular process variable (e.g. path or axis-specific feedrate) as a function of other measured process variables (e.g. spindle current, torque, etc.).

This function can be used, for example, to

- keep the cutting volume constant during grinding
- protect the machine and tool against overloads
- achieve shorter machining times
- achieve a better surface quality.

**Parameterization**

The AC control can be parameterized within the part programming as follows:

- **Additive control**
  
  With the additive control method, the programmed value (F word in the case of AC control) is corrected as an additive function.

  \[ F_{\text{effective}} = F_{\text{programmed}} + F_{\text{AC}} \]

- **Multiplicative control**
  
  In the case of multiplicative control, the F word is multiplied by a factor (override in the case of AC control).

  \[ F_{\text{effective}} = F_{\text{programmed}} \cdot \text{Factor}_{\text{AC}} \]

**Functional schematic of additive control**

![AC additive control diagram](image)

The function is effective within the upper and lower limit. The pitch of straight line

\[ y = mx + n \]

is negative \( \Rightarrow a_1 \) is negative.

**Note:**

\[ \tan \alpha = -p \]

The gain of the control equals the pitch of straight line

\[ a_0 = p \cdot \text{Basis} \]
Example The programmed feed (axial or path-related) shall be controlled by the current (positive) of the x-axis (e.g. infeed moment). The working point is defined at 5 A. The feedrate may be altered by ± 100 mm/min. In this case, the axial current deviation must not exceed ± 1 A.

Definition of coefficients:

\[ y = f(x) = a_0 + a_1 x + a_2 x^2 + a_3 x^3 \]

\[ a_1 = -\frac{100 \text{mm}}{1 \text{min} \cdot \text{A}} \]

\[ a_1 = -100 \Rightarrow \text{control constant} \]

\[ a_0 = -(-100) \cdot 5 = 500 \]

\[ a_2 = 0 \}\text{ (no square element)}\]

\[ a_3 = 0 \}\text{ (no cubic element)}\]

upper limit = 100

lower limit = -100

FCTDEF( <polynomial no.>, <lower_Limit>, <upper_Limit>, <Coeff0>, <Coeff1>, <Coeff2>, <Coeff3> )

FCTDEF(1, -100, 100, 500, -5, 0, 0)

This function describes the example displayed in Fig. 2-12 completely.

AC control is activated with the following synchronized action:

\[ \text{ID} = 1 \text{ DO SYNFCT(1, SAC_VC, SAA_LOAD[x])} \]

Fig. 2-12 Example of additive control

Functional schematic of multiplicative control

Fig. 2-13 AC multiplicative control
The function is effective between the upper limit and the ordinate zero. The working point is located on the curve.

The working point is characterized by

- the base value
- the corresponding factor (with override, standard = 100 %)

From Fig. 2-13, the following results for \( a_0 \):

\[
a_0 = \varepsilon + (b \cdot p)
\]

\( \varepsilon \) ⇒ factor
\( b \) ⇒ base value
\( p \) ⇒ gain

Example

The programmed feed (axial or path-related) shall be controlled multiplicatively. The working point is defined at 100 % with 30 % drive load. With 80 % load, the axis (n) shall stand still. A velocity overshoot of 20 % of the programmed velocity is admitted.

![Fig. 2-14 Example of multiplicative control](image)

Definition of coefficients:

\[
y = f(x) = a_0 + a_1x +a_2x^2 + a_3x^3
\]

\[
a_1 = \frac{100}{(80-30)} = \frac{50}{50} = -2
\]

\[
a_0 = 100 + (2 \cdot 30) = 160
\]

\( a_2 = 0 \) (no square element)

\( a_3 = 0 \) (no cubic element)

upper limit = 120

lower limit = 0

\[
\text{FCTDEF( <polynomial no.>, <lower_Limit>, <upper_Limit>, <Coeff0>, <Coeff1>, <Coeff2>, <Coeff3> )}
\]

\[
\text{FCTDEF(1, 0, 120, 160, -2, 0, 0)}
\]

This function describes the example displayed in Fig. 2-14 completely.

The corresponding synchronization may be

\[
\text{ID = 1 DO SYNFCT(1, $AC_OVR, $AA_LOAD[x])}
\]
2.2 Motion-synchronous actions (up to and including SW 3)

Real-time variables

When the function is activated, programming of the following real-time variables is enabled:

- \( \text{$AA\_LOAD[<\text{axial expression}>]} \) Drive capacity utilization
- \( \text{$AA\_POWER[<\text{axial expression}>]} \) Drive active power
- \( \text{$AA\_TORQUE[<\text{axial expression}>]} \) Drive torque setpoint
- \( \text{$AA\_CURR[<\text{axial expression}>]} \) Current actual value of axis or spindle
- \( \text{$A\_INA[\text{INPUT}]$} \) Input analog value

Example of AC control with an analog input voltage

A process quantity (measured via \( \text{$A\_INA[\text{INPUT}]$} \)) must be regulated to 2 V through correction of the path or axial feedrate by the additive control method. The feedrate override must be adjusted within the \( \pm 100 \text{ [mm/min]} \) range.

As an example of how to implement the "AC control" function, two subprograms to activate the function and one subprogram to deactivate it are described below which implement the AC functionality on the basis of motion-synchronous actions. The machine manufacturer or user can create and modify these programs to meet his own requirements.

Definition of coefficients:

\[ y = f(x) = a_0 + a_1 x + a_2 x^2 + a_3 x^3 \]

- \( a_1 = \frac{-100 \text{ mm}}{1 \text{ min} \cdot 1 \text{ V}} \)
- \( a_1 = -100 \Rightarrow \text{control constant} \)
- \( a_0 = \frac{-(-100)}{2} = 200 \)
- \( a_2 = 0 \) (no square element)
- \( a_3 = 0 \) (no cubic element)
- upper limit = 100
- lower limit = -100

Fig. 2-15 Diagram showing AC control
2.2 Motion-synchronous actions (up to and including SW 3)

FCTDEF( <polynomial no.>, <lower_Limit>, <upper_Limit>, <Coeff0>, <Coeff1>, <Coeff2>, <Coeff3> )
FCTDEF(1, -100, 100, 200, -100, 0, 0)

AC control can be activated with the following synchronized action:
ID = 1 DO SYNFCT(1, $AA_VC[x], $A_INA[1])
2.2 Motion-synchronous actions (up to and including SW 3)

Notes
Supplementary Conditions

Availability of “Constant analog-value output” function

The “Constant analog value output” function (Prerequisite: Analog output) is an option and available for

- SINUMERIK 840D with NCU 572/573, with SW 2 and higher.

Availability of “Adaptive control” function

The function is an option and available for

- SINUMERIK 840D with NCU 572/573, with SW 2 and higher.

The function is contained in the export version 840DE with restricted functionality; it is not contained in the FM-NC, 810DE (SW 3.1 and earlier).

- SINUMERIK 810DE, SW 3.2 and higher

Availability of “Multiple feedrates in a block” function

The function is an option and available for

- SINUMERIK FM-NC with NCU 570, with SW 2 and higher
- SINUMERIK 840D with NCU 572/573, with SW 2 and higher.
- SINUMERIK 810DE, SW 3.2 and higher

Availability of “Laser” function

The function is an option and available for

- SINUMERIK FM-NC with NCU 570, with SW 3.2 and higher
- SINUMERIK 840D with NCU 572/573, SW 3.2 and higher

Availability of “Distance control” function

The function is an option and available for

- SINUMERIK FM-NC with NCU 570, with SW 3.2 and higher
- SINUMERIK 840D with NCU 572/573, SW 3.2 and higher

Availability of “Synchronized actions SW4” function

The new function as of SW 4 is contained in export version 840DE with restricted functionality.

The function is not contained in the export versions FM-NC and 810DE.

SINUMERIK 840Di

This system offers the same functions as the 840D. Special functions that operate on hardware specific to the SINUMERIK 840D, e.g. adaptive control components, are currently available only on request.
Motion-synchronous actions that utilize the listed realtime variables are not configurable on the SINUMERIK 840Di at present:

- $AA\_LOAD$: Drive capacity utilization
- $AA\_POWER$: Drive active power
- $AA\_TORQUE$: Drive torque setpoint
- $AA\_CURR$: Actual current of axis or spindle

**Note**

The motion-synchronous action functionality is provided by the NC of the SINUMERIK 840Di. The requisite realtime variables for function evaluation cannot, however, be transferred to or from the drive/slave via the PROFIBUS-DP.
## Data Descriptions (MD, SD)

### 4.1 Channel-specific machine data

#### MULTFEED_ASSIGN_FASTIN

<table>
<thead>
<tr>
<th>MD number</th>
<th>MULTFEED_ASSIGN_FASTIN</th>
<th>Assignment of input bytes of NCK I/Os for “Multiple feedrates in a block”</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default value: 0</td>
<td>Min. input limit: ***</td>
<td>Max. input limit: ***</td>
</tr>
<tr>
<td>Changes effective after Power On</td>
<td>Protection level: 2/7</td>
<td>Unit: HEX</td>
</tr>
<tr>
<td>Data type: DWORD</td>
<td>Applies from SW version: 2.1</td>
<td></td>
</tr>
</tbody>
</table>

**Significance:**

Acquisition of the following drive actual values is activated by means of MD:

MULTFEED_ASSIGN_FASTIN (assignment of input bytes of NCK I/Os for “Multiple feedrates in a block”). The assigned input signals can also be inverted with this machine data.

The MD is coded as follows:

- **Bits 0–7:** Number of 1st digital input byte or comparator input byte used
- **Bits 8–15:** Number of 2nd digital input byte or comparator input byte used
- **Bits 16–23:** Inverting screen form for writing 1st byte
- **Bits 24–31:** Inverting screen form for writing 2nd byte

- **Bit=0:** Do not invert
- **Bit=1:** Invert

If a 2nd byte is entered, the contents of the 1st and 2 bytes are ORed prior to use.

The following must be specified as digital input numbers:

- 1: for on-board byte
- 2–5: for external bytes

The following must be specified as comparator input byte numbers:

- 128: for comparator 1 (equals 80Hex)
- 129: for comparator 2 (equals 81Hex)

**Application**

The external digital input byte 3 must be used as the 1st byte and the input byte of comparator 2 as the 2nd byte for the “Multiple feedrates in a block” function. The signals must also be inverted:

- **Bit 0, 2, 3 of the digital input byte**
- **Bit 0, 1, 5, 7 of the comparator input byte**

⇒ MD:MULTFEED_ASSIGN_FASTIN=A30D8103 (in Hex format)
## 4.1 Channel-specific machine data

<table>
<thead>
<tr>
<th>MD number</th>
<th>MULTFEED_STORE_MASK</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>21230</strong></td>
<td>Store input signals of “Multiple feedrates in a block” function</td>
</tr>
</tbody>
</table>

### Significance:

- The higher the bit number of the signals for feedrates F2–F7 of the “Multiple feedrates in a block” function, the lower their priority within the input byte. The highest-priority signal determines the current feedrate.
- The response to a reduction in the value applied to the highest-priority input can be defined in MD: MULTIFEED_STORE_MASK (store input signals of “Multiple feedrates in a block” function).
- When bit 2–7 is set, the associated feedrate (F2 to F7) as selected by the highest-priority input signal in each case remains valid even if the input signal drops and a lower-priority input is active.

The MD is coded as follows:

- **Bits 0–1**: No significance
- **Bits 2–7**: Storage of feedrate signals
- **Bits 8–31**: Reserved
### 4.2 Axis/spindle-specific machine data

#### 32070 CORR_VELO
- **MD number**: 32070
- **Default value**: 100
- **Changes effective after Power On**: Changes effective after Power On
- **Protection level**: 0
- **Unit**: %
- **Data type**: DWORD
- **Applies from SW version**: 3.2

**Significance**: Limitation of axis speed for handwheel overlay, external zero offset, continuous dressing, distance control $AA_OFF$ via synchronized actions related to the JOG speed MD: JOG_VELO, MD: JOG_VELO_RAPID, MD: JOG_REV_VELO, MD: JOG_REV_VELO_RAPID.

The maximum admissible speed is the maximum speed in MD: MAX_AX_VELO. Speed limitation is made to this value. An alarm is displayed if this value is exceeded.

The conversion into linear or rotary axis speed is made according to MD: IS_ROT_AX.

**Application**: The velocity is limited with displacement of overlaid movements.

#### 32920 AC_FILTER_TIME
- **MD number**: 32920
- **Default value**: 0.0
- **Changes effective after Power On**: Changes effective after Power On
- **Protection level**: 2/7
- **Unit**: s
- **Data type**: DOUBLE
- **Applies from SW version**: 2.1

**Significance**: The following drive actual values can be acquired with main run variables $AA_LOAD$, $AA_POWER$, $AA_TORQUE$ and $AA_CURR$:
- Drive capacity utilization
- Drive active power
- Drive torque setpoint
- Current actual value of axis or spindle

In order to eliminate peaks, the measured values can be smoothed by means of a PT1 filter. The filter time constant is defined with MD: AC_FILTER_TIME (filter smoothing time constant for adaptive control).

On acquisition of the drive torque setpoint or current actual value, the filter acts in addition to the filters in the 611D. Both filters are connected in series if both strongly and weakly smoothed values are required in the system.

The filter is deactivated by entering a smoothing time of 0 seconds.

**Application**: Smoothing of current actual value for AC control

MD irrelevant for FM-NC with 611A.
### 4.2 Axis/spindle-specific machine data

#### DRIVE_SIGNAL_TRACKING

**36730**

<table>

Brief Description

Software basis

The SINUMERIK FM-NC control is based on the software of the SINUMERIK 840D. All FM-NC-specific functions including the stepper motor control are implemented by additions and modifications to this basis software. This documentation only describes the changes and function additions that are required for stepper motor control.

Note

This Description of Functions applies only to SINUMERIK FM-NC with NCU 570.2 up to SW 3.

Reference point approach

A special procedure is required to acquire the actual position of stepper motors (without measuring system). The measuring system zero pulse is replaced here by a BERO.

Rotation monitoring

In order to monitor the rotary motion of a stepper motor, a rotation monitor can be activated via a VDI interface signal. It is thus possible to monitor the stepping coincidence.

Speed control

To achieve optimum speed control with stepper motors, a knee-shaped acceleration characteristic is required owing to the specific frequency characteristic (start/stop frequency with step change). This is available for positioning tasks. A constant speed time can be set in the machine data to minimize acceleration jumps.

________________________________________________________________________
2.1 Reference point approach for stepper motors

2.1.1 Traversal for referencing

The procedure applied to approach the reference point with an incremental encoder is the same as that used to reference with an analog drive.

MD 30240: ENC_TYPE must be set in accordance with the measuring system type (no feedback of the steps as actual-value pulses).

2.1.2 Defining reference point using a BERO

The basic sequence of referencing operations and the possible settings with machine data are the same as those used for referencing with an incremental encoder, see References: /FB/, R1, “Reference Point Approach”

A BERO replaces the zero pulse of the incremental encoder, which is placed on the motor shaft or spindle. The rising edge of the BERO (single-edge evaluation) or the BERO center (dual-edge evaluation) are used for synchronization.

Procedure

- Phase 1: Approach the reference point cam, see References: /FB/, R1, “Reference Point Approach”
- Phase 2: Synchronization with the reference point BERO (zero pulse simulation), basic procedure, see References: /FB/, R1, “Reference Point Approach”
- Phase 3: Approach reference point see References: /FB/, R1, “Reference Point Approach”

Synchronization with the reference point BERO

A rapid input is required to transfer switching edges to the control system. The FM-NC is equipped with four digital inputs (pins 13 to 16) on connector X1 (connector for handwheel and connection of I/O devices). The rapid digital inputs are permanently assigned to the servo loops.
BERO edge

When the selected BERO edge appears, the corresponding actual-value register is latched.

To obtain a good reduction of the reference point, the search velocity for the BERO edge must not exceed a maximum value depending on the BERO type.

Single-edge evaluation

The positive edge of the BERO is interpreted as a zero pulse.
The selection is made in MD 34200: ENC_REF_MODE = 2.

Dual-edge evaluation

The positive edge and the negative edge of the reference point BERO are traversed one after the other and the actual values for each registered. The mean value is the synchronization point at which phase 2 is completed and phase 3 starts.
The selection is made in MD 34200: ENC_REF_MODE = 4.

With dual-edge evaluation any drift of the BERO edges can be compensated for. The maximum speed is also limited by the fact that the time between the two edges including any switching delay by the BERO must be greater than 1 SERVO cycle.
2.2 Rotation monitoring of stepper motor with BERO

Overview
The BERO used for rotation monitoring is connected in the same way as the BERO for referencing.

It is possible to connect this BERO in parallel with the referencing BERO or use of the same for rotation monitoring. However, rotation monitoring must be deactivated during referencing, i.e. no signal edge is allowed to arrive from the reference BERO while rotation monitoring is active.

Modulo counter
A modulo counter (modulo 1 revolution) counts the actual-value increments.
The modulo count is stored in the machine data.
MD 31100: BERO_CYCLE Repeat cycle of BERO edges in actual-value increments

Activation
Rotation monitoring can be activated and deactivated via IS “Rotation monitoring ON/OFF” (DB31–..., DBX24.0). The BERO is “zeroed” when it is traversed for the first time, the contents of the modulo counter are recorded as the “BERO zeroing value”.

Comparison
Every time the BERO is traversed again, the contents of the modulo counter are compared with the stored “BERO zeroing value” to see if they are similar.

A BERO tolerance which can be set in MD 31110: BERO_EDGE_TOL can be included in the comparison. If the comparison is negative, IS “Error in rotation monitoring” is signaled to the PLC (DB31–..., DBX96.0). The signal has edge evaluation and is only present for the duration of one PLC cycle. At the same time, the monitoring function is switched off automatically and reference point approach has to be repeated.

Note
The “Error in rotation monitoring” always occurs if the stepper motor is activated incorrectly, even if rotation monitoring is not activated. The user must ensure that the drive is switched off safely.
“Error rotation monitoring” means that the drive has to be switched off!

Overview

Modulo counter

Activation

Comparison

Note
2.3 **Speed control**

2.3.1 **Knee-shaped acceleration characteristic**

One of the characteristic features of stepping drives is the drop in the available torque in the upper speed range (see Fig. 2-2).

The best way to achieve optimum loading of motors with such characteristics while protecting them against overloading is to control the acceleration rate as a function of speed.

This method — referred to as a “knee-shaped acceleration characteristic” — can be used for both positioning and path movements.

**Parameterization of axis characteristic**

The axial response of the acceleration characteristic must be parameterized by the following machine data:

- **MA_MAX_AX_VELO**
  Maximum axial speed ($v_{\text{max}}$)

- **MA_ACCEL_REDUCTION_SPEED_POINT**
  Speed at which acceleration rate is reduced with respect to MA_MAX_AX_VELO ($v_{\text{red}}$)

- **MA_MAX_AX_ACCEL**
  Maximum axial acceleration ($a_{\text{max}}$)

- **MA_ACCEL_REDUCTION_FACTOR**
  Acceleration reduction factor with respect to MA_MAX_AX_ACCEL ($a_{\text{red}}$)

- **MA_ACCEL_REDUCTION_TYPE**
  Type of acceleration characteristic
  - 0: Constant
  - 1: Hyperbolic
  - 2: Linear

![Fig. 2-2 Typical motor characteristics of stepping drive](image-url)
Fig. 2-3 Axial acceleration and speed characteristics

**Speeds:**
- $v_{\text{max}}$: MA_MAX_AX_VELO
- $v_{\text{red}}$: MA_ACCEL_REDUCTION_SPEED_POINT \cdot MA_MAX_AX_VELO

**Acceleration rates:**
- $a_{\text{max}}$: MA_MAX_AX_ACCEL
- $a_{\text{red}}$: $(1 - \text{MA_ACCEL_REDUCTION_FACTOR}) \cdot MA_MAX_AX_ACCEL$
Path characteristic

There are no special machine data for the path movement. The characteristic is based on the parameters of the relevant axes as a function of their share of the path vector (geometry). It is possible to combine axes with different acceleration characteristics.

The most restrictive type in each case – regardless of share of the path vector – determines the acceleration characteristic of the path.

The following order of characteristics applies:

1. Constant
2. Hyperbolic
3. Linear
4. None (MA_ACCEL_REDUCTION_SPEED_POINT = 1 or MA_ACCEL_REDUCTION_FACTOR = 0)

It is therefore possible to operate a mixture of stepping and DC drives.

Line-normal and tangential acceleration characteristics are evaluated together within curved path sections.

The path speed is reduced such that a maximum of 25 % of the speed-dependent accelerating capability of the axes is required for line-normal acceleration. The remaining 75 % is reserved for tangential acceleration processes, i.e. deceleration or acceleration on the path.
Equivalent path characteristic

If the path movement cannot be traversed at a velocity-dependent acceleration rate (e.g. kinematic transformation), then the dynamic limit values are reduced. A compromise must be found between maximum speed and constant acceleration (e.g. Fig. 2-4).

Fig. 2-4 Equivalent path characteristic

- $a_N$: Line normal acceleration
- $a_{equ}$: Constant acceleration of equivalent characteristic
- $a_{15\%}$: Minimum constant acceleration
  
  \[ a_{15\%} = 0.15 \times (a_{max} - a_{equ}) + a_{red} \]

- $v_{equ}$: Speed of equivalent characteristic
- $v_{prog}$: Programmed speed
- $v_{15\%a}$: Speed at $a_{15\%}$
- $r$: Radius

If the programmed speed is higher than $v_{15\%a}$, then this value is applied as the limit. A minimum acceleration rate ($a_{15\%}$) is thus ensured.
Activation

The characteristic is activated by means of machine data or NC language commands.

**MA_ACCEL_TYPE_DRIVE = 1**

The knee-shaped acceleration characteristic is the axial basic setting. All specified parameters of the acceleration characteristic must be observed with every type of movement.

Effect:

1. The knee-shaped acceleration characteristic is always active for single axis movements (positioning, oscillation, JOG...).
   
   Switchover to BRISKA (constant acceleration over the entire speed range) or SOFTA (constant jerk) is not permitted.

2. If at least one axis for which MA_ACCEL_TYPE_DRIVE = TRUE is programmed is involved in the path movement and DRIVE is not active, then the dynamic limit values are reduced (equivalent path characteristic).

**NC language commands DRIVE**

Activation of knee-shaped acceleration characteristic for path movement is performed with the language command DRIVE or by means of machine data

**MC_GCODE_RESET_VALUE[20] = 3.**

Value 3 of the MD "MC_GCODE_RESET_VALUE[20]" means that the knee-shaped acceleration characteristic is active after activation.

**MA_ACCEL_TYPE_DRIVE** has no significance in this case.

The path characteristic is determined by the machine data

**MA_ACCEL_REDUCTION_SPEED_POINT**

**MA_ACCEL_REDUCTION_FACTOR**

**MA_ACCEL_REDUCTION_TYPE**

of the relevant axes in combination with the geometry.

Transformation:

The DRIVE acceleration characteristic may not be used in conjunction with an active kinematic transformation. The BRISK characteristic is selected internally instead. If MA_ACCEL_TYPE_DRIVE is set for at least one of the relevant path axes, then the equivalent path characteristic takes effect.

**NC language commands DRIVEA(AXIS).**

Activation of knee-shaped acceleration characteristic for single-axis movements (positioning axes).
Examples of activation:

Machine data:

DRIVE as power ON setting

```
MC_GCODE_RESET_VALUE[20] = 3
```

Parameters of axis characteristic:

X axis

```
MA_ACCEL_REDUCTION_SPEED_POINT[X] = 0.4
MA_ACCEL_REDUCTION_FACTOR[X] = 0.85
MA_ACCEL_REDUCTION_TYPE[X] = 2
MA_ACCEL_TYPE_DRIVE[X] = TRUE
```

Y axis

```
MA_ACCEL_REDUCTION_SPEED_POINT[Y] = 0.0
MA_ACCEL_REDUCTION_FACTOR[Y] = 0.6
MA_ACCEL_REDUCTION_TYPE[Y] = 1
MA_ACCEL_TYPE_DRIVE[Y] = TRUE
```

Z axis

```
MA_ACCEL_REDUCTION_SPEED_POINT[Z] = 0.6
MA_ACCEL_REDUCTION_FACTOR[Z] = 0.4
MA_ACCEL_REDUCTION_TYPE[Z] = 0
MA_ACCEL_TYPE_DRIVE[Z] = FALSE
```

NC program:

```
N10 G1 X100 Y50 Z50 F700 Path movement (X, Y, Z) with DRIVE
N15 Z20 Path movement (Z) with DRIVE
N20 BRISK Switchover to BRISK
N25 G1 X120 Y70 Path movement (Y, Z) with equivalent characteristic
N30 Z100 Path movement (Z) with BRISK
N35 POS[X] = 200 FA[X] = 500 Positioning movement (X) with DRIVEA
N40 BRISKA(Z) Activate BRISKA for Z
N40 POS[Z] = 50 FA[Z] = 200 Positioning movement (Z) with BRISKA
N45 DRIVEA(Z) Activate DRIVEA for Z
N50 POS[Z] = 100 Positioning movement (Z) with DRIVE
N55 BRISKA(X) Causes error message
...
```

**G64 block transition**

Axial speed step changes may occur during non-tangential block transitions.

The path speed at the block transition is reduced if the speed of one path axis is higher than the speed at which the acceleration rate is reduced (MA_ACCEL_REDUCTION_SPEED_POINT).
2.3 Speed control

G64 braking ramp

In the case of short blocks, the acceleration or deceleration process may be executed over several path sections.

In this case, the Look Ahead calculation takes the speed-dependent acceleration characteristic into account.

![Look Ahead braking ramp](image)

**Fig. 2-5** Look Ahead braking ramp

### 2.3.2 Response to acceleration rate changes

**Constant speed time**

MD 20500: CONST VELO_MIN_TIME (minimum time at constant speed) can be programmed to set a time period for which the speed is kept constant in the event of a change from acceleration to deceleration. This function halves any acceleration step change that may occur (e.g. even if the motor stops in an acceleration phase).

**Activation**

This constant speed time is set in MD 20500: CONST VELO_MIN_TIME to a value other than zero and applies to positioning axes (additional axes), spindles and geometry axes.

![Constant-speed phase](image)

**Fig. 2-6** Constant-speed phase

- **v1**: Speed during constant-speed phase
- **v2**: Maximum speed without constant-speed period (not higher than maximum path speed, MD 35220: ACCEL_REDUCTION_SPEED_POINT)
- **t1**: Commencement of constant-speed phase
- **t2**: End of constant-speed phase
- **t3**: Stop instants; \((t2 - t1) = MD 20500: CONST VELO_MIN_TIME\)
2.3.3 Parameterization of stepper motor frequency

**Stepper motor frequency**

The maximum stepper motor frequency is defined with the machine data MD 31350: FREQ_STEP_LIMIT [Hz].

\[
\text{MD 31350 [Hz]} = \frac{\text{Motor speed [rev/min]} \cdot \text{steps per } 360^\circ}{60 \text{ [s]}}
\]

This frequency must coincide with MD32000: MAX_AX_VELO.

**Example:**

\[
\text{MAX_AX_VELO} = \text{Variant a or b [mm/min]}
\]

a) Speed ratio:

\[
\text{Motor speed [rev/min]} \cdot \text{load gear} \cdot \text{spindle pitch [mm]} = \text{axis velocity}
\]

b) Reduction ratio:

\[
\frac{\text{Motor speed [rev/min]} \cdot \text{spindle pitch}}{\text{load gear}} = \text{axis velocity}
\]

**Variant b:**

Motor speed: 1 200 rev/min
Load gear: 1:1
Spindle pitch: 10 mm
Steps per 360°: 10 000

\[
\frac{1 200 \text{ rev/min} \cdot 10 \text{ mm}}{1} = 12 000 \text{ mm/min}
\]

Accordingly, the frequency of MD31350 must be:

\[
\frac{1 200 \text{ rev/min} \cdot 10 000}{60 \text{ s}} = 200 000 \text{ Hz}
\]

**Important**

The frequency must be entered in Hz!

**Stepper motor without encoder**

When the stepper motor is used without an encoder, MD 31020: ENC_RESOL and MD 31400: STEP_RESOL

the number of steps per 360° must be entered.

**Example:**

Stepper motor pulses per 360°: 10 000
MD 31020: ENC_RESOL [0] = 10 000
### Stepper motor with encoder

If a stepper motor is operated with encoder, encoder adaptation is made as with analog drives.

---

**Note**

The number of steps per 360° must be applied to determine MD 31350.

---

**Example**

#### With encoder

- Encoder: 2 500 encoder pulses per revolution
- Stepper motor: 10 000 [pulses per motor rotation]
- Load gear: 1:1
- Spindle pitch: 10 mm
- Motor speed: 1 200 rpm

MD 30130: CTRLOUT_TYPE = 2  
MD 30240: ENC_TYPE = 2 (with TTL encoder)  
MD 31020: ENC_RESOL[0] = 2 500 (pulse quadruplication)  
MD 31350: FREQ_STEP_LIMIT[Hz] = 200 000 [Hz]  
MD 32 000 = 12 000 mm/min

#### Without encoder

- Stepper motor: 10 000 [pulses per motor rotation]
- Load gear: 1:1
- Spindle pitch: 10 mm
- Motor speed: 1 200 rpm

MD 30130: CTRLOUT_TYPE = 2  
MD 30240: ENC_TYPE = 3  
MD 31020: ENC_RESOL[0] = 10 000 (no pulse quadruplication)  
MD 31350: FREQ_STEP_LIMIT[Hz] = 200 000 [Hz]  
MD 32 000 = 12 000 mm/min

---

**Note**

To define the adaptation, please observe that the pulses are quadruplicated if an encoder is used.  
If no encoder is used, MD 30240: ENC_TYPE = 3
# Supplementary Conditions

| Servo gain for SM control without measuring system | The filter of the internal closed-loop system for frequency conversion is rated for a servo sampling time of 5...6 ms at a limit frequency of 60 Hz. (MD 10050: SYSCLOCK_CYCLE_TIME).

</tr>
</tbody>
</table>
When a stepper motor is used as an axis (spindle), VDI signals must be used in the following way:

The “Servo enable” signal is **not used to shut down** the drive via the NC (Drive enable is always active). This affects the following signals:

- Servo enable
- Position measuring system ON/OFF
- Park
- Fault responses

The user is responsible for ensuring that the PLC “safely stops” or shuts down the stepper motor drive concerned.

Machine data $MA_AX_EMERGENCY_STOP_TIME and $MA_SERVO_DISABLE_DELAY_TIME have no effect in stepper motor drives without a measuring system.
## Data Descriptions (MD, SD)

</table>
### 4.1 Axis-specific machine data

#### 35220 MD number

<table>
<thead>
<tr>
<th>ACCEL_REDUCTION_SPEED_POINT</th>
<th>Activation speed/velocity for acceleration reduction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default value: 1.0</td>
<td>Min. input limit: 0.0</td>
</tr>
<tr>
<td></td>
<td>Max. input limit: 1.0</td>
</tr>
<tr>
<td>Changes effective after Power On</td>
<td>Protection level: 2</td>
</tr>
<tr>
<td>Data type: DOUBLE</td>
<td>Unit: --</td>
</tr>
</tbody>
</table>

**Significance:** Effective for spindles and positioning axes. The speed/velocity at which the spindle/axis acceleration rate decreases is set here. The reference speed/velocity is the defined maximum speed/velocity of the spindle/axis. The speed/velocity value entered here is a percentage function of the maximum speed/velocity.

**Example:**
- Maximum speed = 10,000 degrees/s, \( f = 0.7 \). The reduction in acceleration commences at 70% of the maximum speed. The motor accelerates at full capacity in the speed range from 0...6,999.99... degrees/s, and at reduced rate in the speed range from 7,000...10,000 degrees/s.

#### 35230 MD number

<table>

</tr>
<tr>
<td>Changes effective after RESET</td>
<td>Protection level: 2</td>
</tr>
<tr>
<td>Data type: DOUBLE</td>
<td>Unit: --</td>
</tr>
</tbody>
</table>

**Significance:** Effective for spindles and positioning axes. The spindle/axis acceleration rate is reduced by the specified factor from the activation speed/velocity onwards.

**Example:**
- \( a = 50,000 \text{ degrees/s}^2 \), \( v_{\text{in}} = 6,000 \text{ degrees/s} \), \( f = 0.2 \):
  - In the speed range from 0 to 5,999.99 degrees/s, the axis/spindle is accelerated/decelerated at \( a = 50,000 \text{ degrees/s}^2 \).
  - From a speed of 6,000 degrees/s up to maximum speed, the axis/spindle is accelerated/decelerated at \( a = 40,000 \text{ degrees/s}^2 \).

Brief Description

Every CNC requires memory for storing and managing data. This memory can essentially be divided into two areas. One area contains data that doesn’t change, such as the software of the CNC. This type of data can be stored on electronic memory chips such as EPROM. The second area contains data stored on the control by the machine manufacturer or user. This data is stored on electronic memory chips such as RAM. The control system enables a RAM area to be set up by the user for various specifications. This description provides information on the areas of RAM that are available to the user and how they can be set up.

Note
The SRAM memory currently available is shown in the Program operating area in the program overview (dialog line).

2.1 General

**Active file system**
The active file system is the main memory of the CNC. It contains the current system and user data (e.g. machine data) used to operate the control.

**Passive file system**
The passive file system is the memory area in the control system used to buffer data and programs. The passive file system is organized hierarchically, i.e. in directories and subdirectories.

**SRAM**
The term SRAM refers to the static RAM of the control system that is available to the user for backing up data. SRAM is also referred to in this documentation as backup, non-volatile or static memory. The SRAM memory currently available is shown in the Program operating area in the program overview (dialog line).

**DRAM**
The term DRAM refers to the dynamic RAM of the control system that is available to the user. The data used in this area are generated exclusively by the control, are only required for a certain length of time and do not, therefore, require backup. DRAM is also referred to in this documentation as volatile or dynamic memory.
2.2 Memory organization

The following table shows the hardware configuration of the available NC-CPUs:

<table>
<thead>
<tr>
<th>Hardware configuration</th>
<th>D-RAM</th>
<th>S-RAM unbuffered</th>
<th>S-RAM buffered</th>
<th>FLASH</th>
<th>JEIDA</th>
</tr>
</thead>
<tbody>
<tr>
<td>NCU 570</td>

</tr>
</tbody>
</table>

SRAM
SRAM that is available to the user. It can be configured by means of the machine data described in this Description of Functions.

- NCU 570 128 KB
- NCU 571 256 KB/1.5 MB*
- NCU 572 256 KB/1.5 MB*
- NCU 573 256 KB/1.5 MB*
- NCU 573.2 1.5 MB

*) Available as option, see Catalog NC 60.1

The buffered user memory is entered in KB in MD 18230: MM_USER_MEM_BUFFERED. For NCUs with 2 different memory capacities, the standard entry takes the smallest value into account. If the 2.0 MB version is used, then you have to set MD 18230 explicitly to 1900. (Although the gross value is 2000, it is necessary to make a deduction for internal use).

DRAM
The total amount of DRAM available to the user is displayed in MD 18210: MM_USER_MEM_DYNAMIC (dynamic user memory in DRAM). The value is system-dependent and may vary slightly with different software versions.

The memory areas containing the individual data groups, e.g. global user data, channel-specific user data, axis-specific user data, etc., are arranged contiguously in SRAM and DRAM. The size of a data area in use can be configured in the machine data. The order in which the data areas are arranged is permanently defined by the CNC.

Alteration of memory areas
It is evident from the memory organization described above that any changes to the memory areas must affect the data stored. Every time the system powers up, the CNC compares the current requirement for memory with the existing memory space on the basis of machine data for individual data areas. If the comparison establishes that one or more modified data areas require reallocation of the data areas, the memory is reorganized.
Loss of data during memory reorganization

Reorganization of memory areas always causes loss of all the data in the backup memory.

Backed-up data are also lost if the individual memory areas in the SRAM and DRAM in total exceed the available memory space. It is therefore vital to save the data stored on the CNC before modifying the memory configuration. The SRAM memory available for allocation is indicated in machine data with the identifier INFO_FREE_MEM_.

Memory-configuring machine data

The following list shows some of the machine data which affect the memory configuration:

- System-specific memory settings
- Channel-specific memory settings
- Axis-specific memory settings

The modification of machine data for the SRAM belonging to these groups always leads to the loss of data in the backup memory. The name of these machine data begins with MM_ (e.g. MM_NUM_TOA_MODULES).

The number of active channels also affects the memory configuration. If the number of channels is altered, these channels are set up according to the default settings for the channel-specific memory areas when the system is powered up. Since these areas are also in the SRAM, changing the number of channels also leads to a loss of data in the backup user memory.

After a new value has been entered in a machine data which re-allocates the memory area of the SRAM (see Section 2.4), message 4400 “MD alteration will cause reorganization of buffer (data loss!)” is output. This warning indicates that a machine data has been changed, which causes the backup memory to be reorganized when the NCK is powered up, resulting in a loss of all user data stored there. If the memory is to be reorganized and the control contains data which have not been backed up, these should be saved before the next NCK power-up.

Note

The reorganization can be avoided by changing the modified value back to the original value at the time of the last power-up.

Only in exceptional cases does an MD change not cause reorganization of the memory!

In the case of MD 18350: MM_USER_FILE_MM_MINIMUM (minimum part program memory), the memory reorganization is only performed if the remaining RAM is too small.

Loading the memory-configuring standard machine data on the next system power-up through setting system-specific MD 11200: INIT_MD (load standard machine data on next power-up) to 2 causes the backed up user data to be lost if the memory areas are not organized according to the memory default settings before the system power-up process.
2.3 Memory configuration alarms

A modification to the memory allocation that is incorrect or requires memory reorganization causes the output of an alarm message after CNC system power-up. The causes of the faults and the response of the CNC can be summarized as follows:

Alarm 6000

The user memory (static or dynamic) cannot be reallocated because the total memory area available (static or dynamic) is less than the total number of memory areas set by machine data. In this case, all machine data for configuring memory are deleted and assigned their default values. NC machining is no longer possible. This situation is indicated by alarm 6000 “Memory allocation with standard machine data”. It is not possible to pinpoint a particular machine data as the cause of the error in memory allocation. However, it is possible to find the error by altering the machine data for the memory settings one by one. The alarm can be cancelled with RESET. Machining is possible only when the user data have been loaded.

Alarm 6010

After cycle programs, macro definitions or definitions of global user data have been incorporated, alarm 6010 “Channel [name 1] data block [name 2] has not been or is only partially created, error number [identifier]” is output in response to an error. Either the machine data for the corresponding memory areas have been incorrectly configured or the files contain an error. As an example, three files for macro definitions _N_SMAC_DEF, _N_MMAC_DEF and _N_UMAC_DEF contain a total of 30 macro definitions, but the setting in MD 18160: MM_NUM_USER_MACROS (number of macros) restricts the number of macros to 10.

The identifier [name 1] indicates the name of the channel where the error has occurred. The identifier [name 2] indicates the name of the file with the error. The error number is coded as follows with respect to the cause:

<table>
<thead>
<tr>
<th>Error no.</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>No memory available</td>
</tr>
<tr>
<td>2</td>
<td>Maximum no. of symbols exceeded</td>
</tr>
<tr>
<td>3</td>
<td>Index 1 outside permissible value range</td>
</tr>
<tr>
<td>4</td>
<td>Name already exists on channel</td>
</tr>
<tr>
<td>5</td>
<td>Name already exists on NCK</td>
</tr>
<tr>
<td>&gt;100000</td>
<td>Unrecoverable system error</td>
</tr>
</tbody>
</table>

If the error number output is between 1 and 5, the user can eliminate the error himself. In cases where the error number is > 100000, the error is an unrecoverable system error.

Machining is possible when the machine data or files have been corrected, or the changes have been cancelled and the system rebooted.
2.3 Memory configuration alarms

Alarm 6020
The SRAM has been reorganized after a modification to the static memory allocation. All stored data, with the exception of the machine data, have been lost. Alarm 6020 “Machine data altered – memory reallocated” indicates this situation. The SRAM is reallocated when the number of channels on the CNC or the system, channel or axis-specific memory settings for the static memory are altered. The alarm can be cancelled with RESET. Machining can resume when the user data are loaded.

Alarm 6030
The memory area set in MD 18210: MM_USER_MEM_DYNAMIC (user memory in DRAM), MD 18220: MM_USER_MEM_DPR (user memory in dual-port RAM) or MD 18230: MM_USER_MEM_BUFFERED (user memory in SRAM) is larger than the physical memory actually available. In this case, the CNC enters the available memory in the corresponding machine data and displays it with alarm 6030 “User memory limit has been adapted”. In this case, no user data are lost. The alarm can be cancelled with RESET.

Alarm 6000 “Memory allocation with standard machine data” may arise, however, if further machine data were used for the memory allocation assuming that the excessively large data is correct and memory has been allocated over and above the area actually available.
2.4 Memory allocation in SRAM and DRAM

Since in normal practice the SRAM and DRAM memory is only allocated as part of the start-up process, we would recommend the following procedure for allocating memory taking the SRAM as an example:

- Load standard machine data.
- MD 18230: MM_USER_MEM_BUFFERED (user memory in SRAM) is set to a high value (3000). The NCK is then powered up. Alarm 6030 "User memory limit has been adapted" is output and the maximum amount of memory available to the user entered in MD 18230: MM_USER_MEM_BUFFERED. All other memory-configuring machine data are set to their default values.

- Activate the number of channels and axes required, for further details see References: /IAD/ Installation and Start-Up Guide SINUMERIK 840D /IAF/ Installation and Start-Up Guide SINUMERIK FM-NC

- The static memory still available is displayed in MD 18060: INFO_FREE_MEM_STATIC (display of free static memory).

- If the memory default settings do not allocate the memory satisfactorily, then the memory areas can now be re-configured (increase/decrease individual or several areas via machine data) to adapt the memory provided to the requirements on the machine tool.

  Check: Which memory areas require more memory space? Which memory areas are less important for the application in question?

- After the appropriate machine data for the selected memory areas have been set to define memory requirements, the NCK is reset in order to reorganize the memory.

Example of GUD

An example of how to calculate the memory requirements of global user data is given below.

Supplementary conditions

- Machine with 2 channels.
- The following GUD modules are defined:
  - UGUD: User-specific
  - SGUD: Siemens-specific
  - MGUD: Machine manufacturer-specific
  - GUD7: (Contour table stock removal cycle, required for CYCLE95, cycle version 3.4 and higher)
- NCK-specific and channel-specific variables are defined.

NCK variable

<table>
<thead>
<tr>
<th>Type</th>
<th>Values</th>
<th>Memory Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>REAL</td>
<td>2</td>
<td>2 x 8 bytes = 16 bytes</td>
</tr>
<tr>
<td>BOOL</td>
<td>1</td>
<td>1 x 1 bytes = 1 byte</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Total 1 = 17 bytes</td>
</tr>
</tbody>
</table>

Total NCK (no. of values) = 3

CHAN variable

<table>
<thead>
<tr>
<th>Type</th>
<th>Values</th>
<th>Memory Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOOL</td>
<td>2</td>
<td>2 x 1 bytes = 2 bytes</td>
</tr>
<tr>
<td>INT</td>
<td>1</td>
<td>1 x 4 bytes = 4 bytes</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Total 2 = 6 bytes</td>
</tr>
</tbody>
</table>

Total CHAN (no. of values) = 3

6 bytes (total 2) x 2 (no. of channels) = 12 bytes (total 3)

Calculation of memory required

- MD 18120: MM_NUM_GUD_NAMES_NCK = 3 (total NCK)
  Memory space for management of NCK names
  => 3 x 80 bytes = 240 bytes
- MD 18130: MM_NUM_GUD_NAMES_CHAN = 3 (total CHAN)
  Memory space for management of CHAN names
  => 3 x 80 bytes = 240 bytes
- Number of max. defined GUD modules = 7 (GUD7)
  Memory space for management of GUD modules
  => 7 x 120 bytes = 840 bytes
- Memory requirements for variables
  Total 1 + total 3 =
  17 bytes + 12 bytes = 29 bytes, rounded up to whole KB gives:
  MD 18150: MM_GUD_VALUES_MEM = 1
- Total memory space required for GUD is calculated as:
  Memory space for management of NCK names = 240 bytes
  Memory space for management of CHAN names = 240 bytes
  Memory space for management of GUD modules = 840 bytes
  Memory space required for variables = 1024 bytes
  Total = 2344 bytes

2.4.2 Memory allocation DRAM

- The dynamic memory still available is displayed in MD 18050: INFO_FREE_MEM_DYNAMIC (display data of available dynamic memory).

- If the memory default settings do not allocate the memory satisfactorily, then the memory areas can now be re-configured (increase/decrease individual or several areas via machine data) to adapt the memory provided to the requirements on the machine tool.
  
  Check: Which memory areas require more memory space? Which memory areas are less important for the application in question?

- After the appropriate machine data for the selected memory areas have been set to define memory requirements, the NCK is reset in order to reorganize the memory.

**Note**

If more dynamic memory is demanded than the amount actually available, the SRAM(!) is also automatically deleted during the next power-up and all machine data for the memory configuration reset to their default values.

<td></td>
</tr>
<tr>
<td>MD 28020: MM_NUM_LUD_NAMES_TOTAL</td>
<td>150 bytes per LUD name</td>
<td>See following example</td>
</tr>
<tr>
<td>MD 28040: MM_LUD_VALUES_MEM</td>
<td>Total memory space required for LUD</td>
<td>See following example</td>
</tr>
</tbody>
</table>
Local user data defined in the part programs are stored in the DRAM while the program in which they are defined is being executed. An example of how to calculate the memory requirements of local user data is given below.

The following variables must be used:

1. REAL value → 1 x 8 bytes = 8 bytes
2. BOOL values → 2 x 1 bytes = 2 bytes
   Total 1 = 10 bytes
3. = Total A (no. of values)

The machine data must be set according to the variable that requires the most memory space. In this above example, this is the REAL value with 8 bytes.

MD 28020: MM_NUM_LUD_NAMES_TOTAL = 3 (total A)
Memory space for management of LUD NAMES
=> 3 x 150 bytes = 450 bytes

MD 28040: MM_LUD_VALUES_MEM
Total memory space required for LUD is calculated as:
Memory space for management of LUD NAMES = 450 bytes
Memory space required for variables = 10 bytes
Total = 456 bytes

The calculated sum must be rounded in KB and entered in MD 28040: MM_LUD_VALUES_MEM (in this case, 1 KB).
The memory provided by this setting is allocated in blocks of 8 bytes each in size (according to MD 18242).
If, for example, 1 REAL value (8 bytes) and 1 BOOL value (1 byte) are used in a program, then 2 blocks of memory are assigned 8 bytes each.
2.4 Memory allocation in SRAM and DRAM

**LUD defined in part programs**
Local user data defined in part programs are stored in the DRAM while the program in which they are defined is being executed. During this period, it is possible to view the assigned values under the softkey PARAMETER.

**Definition of variables in PP**
- DEF INT LUD_VARIABLE1 Integer variable with the name VARIABLE1
- DEF REAL LUD_VARIABLE2 REAL variable with the name VARIABLE2

**Memory management**
The system automatically controls the allocation of memory blocks.
- Reservation of a memory block when a part program containing the LUD definition is processed.
- Reservation of further blocks if the memory provided for the number of variables is not sufficient.
- Release of memory space if LUDs are not longer required (at end of program).

**Variants of variable definition**
When a large number of variables is required, e.g. 20 REAL variables, it is possible to save memory space by defining an ARRAY (field) at the beginning of a part program rather than defining each variable individually.

**Example:**

**Case1**
DEF REAL LUD_PAUL[19]
This field with 20 LUD variables PAUL[0] – PAUL[19] requires the following memory space:

MD 28080 = 1 \[\Rightarrow 1 \times 150 \text{ bytes} = 150 \text{ bytes}\]
Memory for 20 variables \[\Rightarrow 20 \times 8 \text{ bytes} = 160 \text{ bytes}\]
Total memory required by 20 variables = 310 bytes

**Case2**
Individual definition of 20 variables: PAUL0, PAUL1 – PAUL19

MD 28080 = 20 \[\Rightarrow 20 \times 150 \text{ bytes} = 3000 \text{ bytes}\]
Memory for 20 variables \[\Rightarrow 20 \times 8 \text{ bytes} = 160 \text{ bytes}\]
Total memory required by 20 variables = 3160 bytes

**Note**
This alternative method of variables definition can also be applied to GUD variables.

See MD 18242: MM_MAX_SIZE_OF_LUD_VALUES for LUD variables

</tbody>
</table>
2.5 Memory requirements calculation

Note
The memory required depends on the software version and type of NC control. The values specified in the table below for the change in memory requirements based on changes in machine data are intended as standard values for SW 4 and NCU 572. The standard values and machine data limits for other software versions or other NC controls can be found in:
References: /LIS/, Lists (of software versions used)

Overview
The tables are arranged in the following order:

- DRAM
  - General machine data
  - Channel-specific machine data
  - Axis-specific machine data

- SRAM
  - General machine data
  - Channel-specific machine data
  - Axis-specific machine data
### Table entries

1. **MD no.**
   Number of the machine data. The associated identifier can be looked up in /LIS/.

2. **Meaning**
   Meaning of the machine data.
   New line:
   - **GD**: Basic DRAM overhead, **GS**: Basic SRAM overhead
   (This overhead is produced when the function controlled by the MD is used. Values are only specified for MDs which are not directly proportional to the value specified in column 3 or which cannot be calculated.)

3. **Default value** (def)
   Value set when the software is supplied.

4. **Increase def. by 1, extra req. (bytes)**
   Specifies the number of bytes by which the memory requirement changes if the default value is increased by 1.
   The basic overheads for GD and GS specified in column 2 are included in the changes shown.

5. **Increase def. by further (n)**
   Specifies by how many additional units the value of the machine data was increased in the capacity calculation. The increased memory allocation is specified in column 6.

6. **Extra requirement for n, (bytes)**
   Specifies how much additional memory is required if the machine data is increased by the value specified in column 5.
   The basic overheads for GD and GS specified in column 2 are included in the changes shown.

7. **SRAM also affected**
   **DRAM also affected**
   An x appears in the column if the other type of memory is also occupied proportionally.

---

**Note**

The actual dependencies between machine data and required memory are complex. Some MD initiate further functions which also use memory. The relationship between the amount of memory used and the number in the MD is not always linear. The tables below therefore only provide an approximate indication of where memory can be reduced or increased in order to achieve the desired configuration. The information applies both to increasing and reducing the values specified in the machine data.

Data Descriptions (MD, SD)

4.1 General machine data

<table>
<thead>
<tr>
<th>MD number</th>
<th>INFO_FREE_MEM_DYNAMIC</th>
</tr>
</thead>
<tbody>
<tr>
<td>Display data of free dynamic memory</td>
<td></td>
</tr>
</tbody>
</table>

Default value: –

Changes effective after Power On: –

Protection level: 0

Min. input limit: –

Max. input limit: –

Unit: byte

Data type: DWORD

Applies from SW version: 1.1

Significance:
The data is used to display the number of bytes available in the dynamic memory. The data cannot be defined. The display is updated with every NCK power-up. Procedure for determining the required memory manually:

- Increase the input value by 1
- Power up the NCK
- Read off the memory requirements
- Calculate possible increase

The content of the machine data specifies the amount of dynamic RAM currently available via MD for the expansion of the volatile user data areas. Before expanding a parameter, such as the number of local user data (LUD), it is advisable to check that sufficient memory is available.

Special cases:
If more dynamic memory is requested than is currently available, the SRAM is deleted on the next power-up and all machine data are initialized with the default settings.
### 18060 INFO_FREE_MEM_STATIC

<table>
<thead>
<tr>
<th>MD number</th>
<th>Description</th>
<th>Default value</th>
<th>Min. input limit</th>
<th>Max. input limit</th>
<th>Changes effective after Power On</th>
<th>Data type</th>
<th>Protection level</th>
<th>Protection level</th>
<th>Unit</th>
<th>Applies from SW version</th>
</tr>
</thead>
<tbody>
<tr>
<td>18060</td>
<td>Display data of free static memory</td>
<td>–</td>
<td>–</td>
<td>–</td>
<td>Changes effective after Power On</td>
<td>DWORD</td>
<td>0</td>
<td>0</td>
<td>byte</td>
<td>1.1</td>
</tr>
</tbody>
</table>

**Significance:**

The contents of the machine data indicate how much non-volatile memory is available for the passive file system at the time of the power-up. Then the value is no longer updated. To determine the current value at any given time the following operations are available:

- MMC102: services of programming: free memory NCK
- MM100: programming; softkey memory info.

If MDs that influence the amount of backed-up memory required are altered, then the amount of memory available for the passive file system also changes since the amount of memory allocated to the passive file system consists of the memory setting in MD 18230: MM_USER_MEM_BUFFERED (SRAM user memory) minus all other backup user data (see also description of MD 18350: MM_USER_FILE_MEM_MINIMUM (minimum part program memory)).

The data cannot be defined. The display is only updated after every NCK power-up.

**Special cases:**

If more static memory is requested than is currently available, the SRAM is deleted on the next power-up and all machine data are initialized with the default settings.

### 18070 INFO_FREE_MEM_DPR

<table>
<thead>
<tr>
<th>MD number</th>
<th>Description</th>
<th>Default value</th>
<th>Min. input limit</th>
<th>Max. input limit</th>
<th>Changes effective after Power On</th>
<th>Data type</th>
<th>Protection level</th>
<th>Protection level</th>
<th>Unit</th>
<th>Applies from SW version</th>
</tr>
</thead>
<tbody>
<tr>
<td>18070</td>
<td>Display data of free memory in DUAL_PORT RAM</td>
<td>–</td>
<td>–</td>
<td>–</td>
<td>Changes effective after Power On</td>
<td>DWORD</td>
<td>0</td>
<td>0</td>
<td>byte</td>
<td>2</td>
</tr>
</tbody>
</table>

**Significance:**

None

**MD irrelevant for ......**

The functionality is not available with SW 2.
### 18080

<table>
<thead>
<tr>
<th>MD number</th>
<th>MM_TOOL_MANAGEMENT_MASK</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Screen form for reserving memory for TM function</td>
</tr>
</tbody>
</table>

**Default value:** 00H  
**Min. input limit:** 00H  
**Max. input limit:** FFFFH  
**Changes effective after Power On:**  
**Protection level:** 1  
**Unit:** –  
**Applies from SW version:** 2  
**Data type:** DWORD

**Significance:**  
Step-by-step TM-specific memory reservation is implemented on a bit-coded basis by this MD. Reservation of individual memory areas is defined by the following MDs:
- MD 18086: MM_NUM_MAGAZINE_LOCATION
- MD 18096: MM_NUM_CC_TOA_PARAM
- MD 18094: MM_NUM_CC_TDA_PARAM
- MD 18098: MM_NUM_CC_MON_PARAM
- MD 18092: MM_NUM_CC_MAGLOC_PARAM
- MD 18090: MM_NUM_CC_MAGAZINE_PARAM

Memory cannot be reserved simply by presetting the individual memory-configuring machine data. The memory configuration is not changed until the appropriate machine data is activated during the next power ON.

**Bit 1:** Make tool management data available:
- Memory-reserving MD for basic functionality of tools must be set:
  - MD 18092: MM_NUM_TOOL
  - MD 18100: MM_NUM_CUTTING_EDGES_IN_TOA
- Memory-reserving MD for tool management function must be set:
  - MD 18086: MM_NUM_MAGAZINE_LOCATION
  - MD 18084: MM_NUM_MAGAZINE

When bit 1 is set, TM-specific memory is added to the memory space defined in MM_NUM_TOOL.

**Bit 2:** Make tool monitoring data available:
- Memory-reserving MD for basic functionality of tools must be set:
  - MD 18092: MM_NUM_TOOL
  - MD 18100: MM_NUM_CUTTING_EDGES_IN_TOA

When bit 2 is set, memory for monitoring data is made available. TM-specific memory is added to the memory space programmed in MD 18100: MM_NUM_CUTTING_EDGES_IN_TOA.

**Bit 3:** OEM/CC data available:
- Memory-reserving MD must be set:
  - MD: MM_NUM_CC_...

When bit 3 is set, memory is made available for OEM applications.

**Bit 4:** "Consider adjacent location" tool management:
- Make memory available for TM function "Consider adjacent location"

**Special cases, errors, ....**  
The backup data are lost if this machine data is altered!

**Related to ...**  
- MD 18084: MM_NUM_MAGAZINE (number of magazines that the NCK can manage)
- MD 18086: MM_NUM_MAGAZINE_LOCATION (number of magazine locations that the NCK can manage)
- MD 18090: MM_NUM_CC_MAGAZINE_PARAM (number of magazine data that are set up and evaluated by the CC)
- MD 18092: MM_NUM_CC_MAGLOC_PARAM (number of magazine location data that are set up and evaluated by the CC)
- MD 18094: MM_NUM_CC_TDA_PARAM (number of tool-specific data per tool for OEM and compile cycle)
- MD 18096: MM_NUM_CC_TOA_PARAM (number of data per tool cutting edge for OEM and compile cycle)
- MD 18098: MM_NUM_CC_MON_PARAM (number of monitoring data per tool cutting edge for OEM and compile cycle)

**References**

## 4.1 General machine data

### 18082 MM_NUM_TOOL

<table>
<thead>
<tr>
<th>MD number</th>
<th>Number of tools managed by the NCK</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default value: 30</td>
<td>Min. input limit: 0</td>
</tr>
<tr>
<td>Changes effective after Power On</td>
<td>Protection level: 2</td>
</tr>
<tr>
<td>Data type: DWORD</td>
<td>Applies from SW version: 2</td>
</tr>
</tbody>
</table>

**Significance:**
The NC cannot manage more tools than the maximum number entered in the MD. One tool has at least one cutting edge.

**Special cases, errors, ......**
The maximum number of possible tools corresponds to the number of cutting edges.

This MD must be set even if no tool management function is used.

The backup data are lost if this machine data is altered!

**Related to ....**
MD 18100: MM_NUM_CUTTING_EDGES_IN_TOA (number of tool offsets in NCK)

### 18084 MM_NUM_MAGAZINE

<table>
<thead>
<tr>
<th>MD number</th>
<th>Number of magazines managed by the NC</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default value: 3</td>
<td>Min. input limit: 0</td>
</tr>
<tr>
<td>Changes effective after Power On</td>
<td>Protection level: 2</td>
</tr>
<tr>
<td>Data type: DWORD</td>
<td>Applies from SW version: 2</td>
</tr>
</tbody>
</table>

**Significance:**
The number of magazines which NCK can manage.

The MDs for TM MD 20310: TOOL_MANAGEMENT_MASK, MD 18080: MM_TOOL_MANAGEMENT_MASK and the optional TM $ON_TECHNO_FUNCTION_MASK must be set.

**MD irrelevant for ......**
MD is irrelevant if the tool management function is not in use.

**Special cases, errors, ......**
Only tool management stage 2:

Value = 0 → tool management stage 2 cannot be activated because no memory area has been set up for the data.

The backup data are lost if this machine data is altered!

**Related to ....**
MD 18080: MM_TOOL_MANAGEMENT_MASK (screen form for reserving memory for TM function)
MD 20310: TOOL_MANAGEMENT_MASK (activation of different variants of tool management function)
$ON_TECHNO_FUNCTION_MASK

/FBW/, Description of Functions, Tool Management

### 18086 MM_NUM_MAGAZINE_LOCATION

<table>
<thead>
<tr>
<th>MD number</th>
<th>Number of magazine locations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default value: 30</td>
<td>Min. input limit: 0</td>
</tr>
<tr>
<td>Changes effective after Power On</td>
<td>Protection level: 2</td>
</tr>
<tr>
<td>Data type: DWORD</td>
<td>Applies from SW version: 2</td>
</tr>
</tbody>
</table>

**Significance:**
The number of magazines which NCK can manage.

The MDs for TM MD 20310: TOOL_MANAGEMENT_MASK, MD 18080: MM_TOOL_MANAGEMENT_MASK and the optional TM $ON_TECHNO_FUNCTION_MASK must be set.

**MD irrelevant for ......**
MD is irrelevant if the tool management function is not in use.

**Special cases, errors, ......**
Only tool management stage 2:

Value = 0 → tool management stage 2 cannot be activated because no memory area has been set up for the data.

The backup data are lost if this machine data is altered!

**Related to ....**
MD 18080: MM_TOOL_MANAGEMENT_MASK (screen form for reserving memory for TM function)
MD 20310: TOOL_MANAGEMENT_MASK (activation of different variants of tool management function)
$ON_TECHNO_FUNCTION_MASK

### 18098  MM_NUM_CC_MON_PARAM

<table>
<thead>
<tr>
<th>MD number</th>
<th>MM_NUM_CC_MON_PARAM</th>
</tr>
</thead>
<tbody>
<tr>
<td>TM compile cycles: Number of monitor data</td>
<td></td>
</tr>
</tbody>
</table>

Default value: 0
Min. input limit: 0
Max. input limit: 10

Changes effective after Power On | Protection level: 2 | Unit: – |

Data type: DWORD
Applies from SW version: 2

Significance: For tool management compile cycles:
Number of monitor data which are created for each tool and which can be evaluated by compile cycles.

MD irrelevant for...... MD is irrelevant if tool management function is not activated.

Special cases, errors,...... The backup data are lost if this machine data is altered!

Related to....
- MD 18080: MM_TOOL_MANAGEMENT_MASK (screen form for reserving memory for TM function)
- MD 18100: MM_NUM_CUTTING_EDGES_IN_TOA (number of tool offsets in NCK)

### 18100  MM_NUM_CUTTING_EDGES_IN_TOA

<table>
<thead>
<tr>
<th>MD number</th>
<th>MM_NUM_CUTTING_EDGES_IN_TOA</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of tool offsets in NCK</td>
<td></td>
</tr>
</tbody>
</table>

Default value: 30
Min. input limit: 0
Max. input limit: 600

Changes effective after Power On | Protection level: 2 | Unit: – |

Data type: DWORD
Applies from SW version: 1.1

Significance: Defines the number of tool cutting edges in the NCK. This machine data reserves approximately 250 bytes of backup memory per TOA module for each tool edge, irrespective of the tool type.

Special cases, errors,...... The backup data are lost if this machine data is altered.

SINUMERIK 840D/840Di/810D/FM-NC Extension Functions (FB2) – 04.00 Edition
### 18118
**MD number** MM_NUM_GUD_MODULES
**Number of GUD modules**

<table>
<thead>
<tr>
<th>Default value: 3</th>
<th>Min. input limit: 1</th>
<th>Max. input limit: 9</th>
</tr>
</thead>
<tbody>
<tr>
<td>Changes effective after Power On</td>
<td>Protection level: 2</td>
<td>Unit: –</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Data type: DWORD</th>
<th>Applies from SW version: 2</th>
</tr>
</thead>
</table>

**Significance:**
A GUD block corresponds to a file in which user-defined data can be stored. 9 GUD blocks are available of which 3 are already assigned to specific users/applications.
- UGUD_DEF_USER (block for user)
- SGUD_DEF_USER (block for SIEMENS)
- MGUD_DEF_USER (block for machine manufacturer)

**Special cases, errors, ......**
The number of GUD modules is determined by the GUD with the highest number.

**Example:** If the following GUD modules are defined,
- UGUD
- MGUD
- GUD5
- GUD8

then the machine data must be set to a value of 8, signifying a memory requirement of $8 \times 120$ bytes = 960 bytes.

It is therefore advisable to selected the "lowest" possible GUD module. If GUD modules UGUD and MGUD have not been assigned elsewhere, then they may be used for this purpose.

**Related to:**
- MD 18150: MM_GUD_VALUES_MEM (memory for user variables)

### 18120
**MD number** MM_NUM_GUD_NAMES_NCK
**Number of global user variables**

<table>
<thead>
<tr>
<th>Default value: 10</th>
<th>Min. input limit: 0</th>
<th>Max. input limit: 400</th>
</tr>
</thead>
<tbody>
<tr>
<td>Changes effective after Power On</td>
<td>Protection level: 2</td>
<td>Unit: –</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Data type: DWORD</th>
<th>Applies from SW version: 1.1</th>
</tr>
</thead>
</table>

**Significance:**
Defines the number of user variables for NCK global user data (GUD). Approximately 8 bytes of memory per variable are reserved in the SRAM for the name of the variable. The additional memory required for the value of the variable depends on the data type of the variable. The number of available NCK-global user variables is restricted by the limit value set in MM_NUM_GUD_NAMES_NCK or MD 18150: MM_GUD_VALUES_MEM (memory for user variables) is reached.

**Special cases, errors, ......**
The backup data are lost if this machine data is altered.

**Related to:**
- MD 18150: MM_GUD_VALUES_MEM (memory for user variables)

### 18130
**MD number** MM_NUM_GUD_NAMES_CHAN
**Number of channel-specific user variables**

<table>
<thead>
<tr>
<th>Default value: 10</th>
<th>Min. input limit: 0</th>
<th>Max. input limit: 200</th>
</tr>
</thead>
<tbody>
<tr>
<td>Changes effective after Power On</td>
<td>Protection level: 2</td>
<td>Unit: –</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Data type: DWORD</th>
<th>Applies from SW version: 1.1</th>
</tr>
</thead>
</table>

**Significance:**
Defines the number of user variables for channel-specific global user data (GUD). Approximately 8 bytes of memory per variable are reserved in the SRAM for the name of the variable. The additional memory required for the variable value is equal to the size of the data type of the variable multiplied by the number of channels. This means that each channel has its own memory available for the variable values. The number of channel-specific, global user variables available is exhausted when the limit defined in MD 18130: MM_NUM_GUD_NAMES_CHAN or MD 18150: MM_GUD_VALUES_MEM (memory for user variables) is reached.

**Special cases, errors, ......**
The backup data are lost if this machine data is altered.

**Related to:**
- MD 18150: MM_GUD_VALUES_MEM (memory for user variables)
18140

<table>
<thead>
<tr>
<th>MD number</th>
<th>MM_NUM_GUD_NAMES_AXIS</th>

<tr>
<td>STRING</td>
<td>1 byte per character, 100 characters permitted per string</td>
</tr>
<tr>
<td>AXIS</td>
<td>4 bytes</td>
</tr>
<tr>
<td>FRAME</td>
<td>400 bytes</td>
</tr>
</tbody>
</table>

The specified value reserves memory for the variables of the global user data (GUD). The dimensioning of the memory depends to a large extent on the data types used for the variables.

Overview of memory used by data types:

The total memory required by channel or axis-specific global user data is the memory used by the variables multiplied by the number of channels or axes.

The number of global user variables available is exhausted when the limits defined in the MD: MM_NUM_GUD_NAMES_xxxx or MM_GUD_VALUES_MEM are reached.

The battery-backed memory is used.

Special cases, errors, ......  The backup data are lost if this machine data is altered!

Related to ....
MD 18118: MM_NUM_GUD_MODULES: (number of GUD modules)
MD 18120: MM_NUM_GUD_NAMES_NCK (number of global user variables)
MD 18130: MM_NUM_GUD_NAMES_CHAN (number of channel-specific user variables)

18160

<table>
<thead>
<tr>
<th>MD number</th>
<th>MM_NUM_USER_MACROS</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Number of macros</td>
</tr>
</tbody>
</table>

Default value: 10  Min. input limit: 0  Max. input limit: 100
Changes effective after Power On  Protection level: 2  Unit: –
Data type: DWORD  Applies from SW version: 1.1

Significance:

Defines the total number of macros which can be stored in the files _N_SMAC_DEF, _N_NMAC_DEF and _N_UMAC_DEF. When opened, each of these files requires at least one KB of memory for the file code. If this limit for the file code is exceeded, another Kbytes is reserved for the file.

Dynamic user memory is used. Approximately 375 bytes per macro are reserved for the specified number of macros for management tasks.

Special cases, errors, ......  The backup data are lost if this machine data is altered.
### 18170

**MD number:** MM_NUM_MAX_FUNC_NAMES

<table>
<thead>
<tr>
<th>Default value: 30</th>
<th>Min. input limit: 0</th>
<th>Max. input limit: 50</th>
</tr>
</thead>
<tbody>
<tr>
<td>Changes effective after Power On</td>
<td>Protection level: 2</td>
<td>Unit: --</td>
</tr>
</tbody>
</table>

**Data type:** DWORD

**Significance:**
- The machine data limits the maximum number of miscellaneous functions over and above the predefined functions (such as sine, cosine, etc.) which can be used in cycle programs.
- The function names are entered in the global NCK dictionary and may not conflict with the names that already exist.
- The SIEMENS cycle package of SW 1 contains miscellaneous functions that are taken into account by the default setting of the MD.
- The data are stored in volatile memory. Approximately 150 bytes are required for each miscellaneous function for management purposes.

**Related to:**
- MD 18180: MM_NUM_MAX_FUNC_PARAM (no. of miscellaneous function parameters)

### 18180

**MD number:** MM_NUM_MAX_FUNC_PARAM

<table>
<thead>
<tr>
<th>Default value: 300</th>
<th>Min. input limit: 0</th>
<th>Max. input limit: 500</th>
</tr>
</thead>
<tbody>
<tr>
<td>Changes effective after Power On</td>
<td>Protection level: 2</td>
<td>Unit: --</td>
</tr>
</tbody>
</table>

**Data type:** DWORD

**Significance:**
- Defines the maximum number of parameters required for the miscellaneous functions in cycle programs.
- 50 parameters are required for the miscellaneous functions of the Siemens cycle package of SW 1.
- The data are stored in volatile memory. Approximately 72 bytes are required for each parameter.

**Related to:**
- MD 18170: MM_NUM_MAX_FUNC_NAMES (number of miscellaneous functions)

### 18190

**MD number:** MM_NUM_PROTECT_AREA_NCK

<table>
<thead>
<tr>
<th>NCU 570: 0</th>
<th>NCU 571: 0</th>
<th>NCU 572: 0</th>
<th>NCU 573: 0</th>
</tr>

<td>810D_2: –</td>
<td>810D_2: –</td>
</tr>
</tbody>
</table>

Changes effective after Power On: Protection level: 2/7 | Unit: KB
---|---|---|
Data type: DWORD | Applies from SW version: 1.1

**Significance:**

The DRAM which physically exists in the NC is used jointly by the system and the user. **MM_USER_MEM_DYNAMIC** defines the amount of memory in the D-RAM that is available to the user. The input limits are dependent on the hardware and software configuration of the CNC.

This memory area contains various types of user data such as:
- local user data
- REORG-LOG data.

The data in the dynamic memory are not backed up.

The input limits ensure that the memory space reserved does not exceed the amount of memory which is actually available in the hardware.

**Application**

When the default values are set, the following DRAM memory is available to the user with the NCU 572/573 depending on the number of defined channels:
- Approx. 1 MB (1 channel defined)
- Approx. 300 KB (2 channels defined).

**Special cases, errors, ......**

During power-up, the system software compares the total demands for DRAM with the value set in MD: **MM_USER_MEM_DYNAMIC**. If the memory required exceeds the capacity defined in the machine data, alarm 6000 "Memory allocation with standard machine data" is output.

Alarm 6030 "User memory limit has been adjusted" is output if the control system detects during power-up that the memory capacity requested through MM_USER_MEM_DYNAMIC is greater than the physical memory size.

**Related to:**

The available dynamic memory is displayed in MD 18050: INFO_FREE_MEM_DYNAMIC (display data for available DRAM).

#### 18220

<td>NCU 570: 238</td>
<td>NCU 570: 100</td>
<td>NCU 570: 238</td>
</tr>
<tr>
<td>NCU 571: 480</td>
<td>NCU 571: 100</td>
<td>NCU 571: 1900</td>
</tr>
<tr>
<td>NCU 572: 480</td>
<td>NCU 572: 100</td>
<td>NCU 572: 1900</td>
</tr>
<tr>
<td>NCU 573: 480</td>
<td>NCU 573: 100</td>
<td>NCU 573: 1900</td>
</tr>
</tbody>
</table>

**Changes effective after Power On**

Protection level: 2

Unit: KB

**Data type: DWORD**

Applies from SW version: 1.1

**Significance:**

Defines the size of the battery-backed user memory. Various types of user data are stored in this area such as, for example:

- NC part programs
- R parameters
- Tool data
- User macros
- Global user data

The settable values are dependent on the hardware and software configurations.

512 KB are available in the hardware for the NCU 571.

512 KB or 2 MB are available for the NCU 572/573 depending on the hardware configuration.

The CNC requires approximately 30 KB of this for its operating system, leaving 480 KB. Some of this remaining memory is allocated for further areas permanently reserved for machine data, setting data and data management.

The CNC manufacturer guarantees 256 KB user memory in the SRAM.

The availability of more than 256 KB user memory cannot be guaranteed in conjunction with the following software versions.

**SRAM with 2 MB:**

If the NCU 572/573 is used with a larger memory, then the memory must be released.

- Enter the value 1900 in MD 18230
- Make a copy of a series start-up file
- Execute POWER ON (in order to reorganize the memory)
- Load the series start-up file back into the control system

During power-up, the system software compares the total amount of battery-backed memory required with the value set in MD 18230: MM_USER_MEM_BUFFERED. If the memory required exceeds the capacity defined in the machine data, alarm 6000 “Memory allocation with standard machine data” is output. Alarm 6030 “User memory limit has been adjusted” is output if the control system detects during power-up that the memory capacity requested in MD 18230: MM_USER_MEM_BUFFERED is larger than the physical memory.

**Special cases, errors, ......**

The backup data are lost if this machine data is altered!
### MM_LUD_HASH_TABLE_SIZE

**Hash table size for user variables**

<table>
<thead>
<tr>
<th>MD number</th>
<th>Significance:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default value: 11</td>
<td>Defines the memory size for local user data (LUD). The value entered must be a prime number. The setting allows the optimization of:</td>
</tr>
<tr>
<td></td>
<td>– the interpreter execution time (smaller value = larger execution time)</td>
</tr>
<tr>
<td></td>
<td>– memory requirements (smaller value = less dynamic memory).</td>
</tr>
<tr>
<td></td>
<td>A larger table requires a smaller number of decoding operations for decoding the variables and consequently a shorter interpreter execution time. The value set in this machine data affects the amount of dynamic memory required for the management of the modules for the local user variables with REORG, see MD 28010: MM_NUM_REORG_LUD_MODULES (number of modules for local user variables with REORG (DRAM)).</td>
</tr>
</tbody>
</table>

**Note:** This machine data is assigned internally by the control and must not be altered by the user.
### 18242

**MD number**: MM_MAX_SIZE_OF_LUD_VALUE  
**Maximum field size of LUD variables**

| Default value: 8192 | Min. input limit: 128 | Max. input limit: 8192 |
| Default setting: 496 (from SW4.1) | SW4.1 | 496 (from SW4.1) |

**Changes effective after Power On**: Protection level: 2  
**Unit**: byte  
**Data type**: DWORD  
**Applies from SW version**: 2

**Significance**:  
MD 18242: MM_MAX_SIZE_OF_LUD_VALUE specifies the block size in which the total memory defined in MD 28040: MM_LUD_VALUES_MEM is assigned to the part programs of the channel. The first variable to occur in the part program occupies a block of the size specified in MD 18242: MM_MAX_SIZE_OF_LUD_VALUE. The following variables are also stored in this block. If the block is full of values or cannot accommodate any further variable, then another block is requested.

MD 18242: MM_MAX_SIZE_OF_LUD_VALUE must be set to the same value as the memory required by the largest possible variable used.

**Data type** | Memory used  
--- | ---  
REAL | 8 bytes  
INT | 4 bytes  
BOOL | 1 byte  
CHAR | 1 byte  
STRING | 1 byte per character, 100 characters permitted per string  
AXIS | 4 bytes  
FRAME | 400 bytes

**Related to**: MD 28040: MM_LUD_VALUES_MEM (memory size for local user variables (DRAM))

**Special cases, errors, .....**: The backup data are lost if this machine data is altered!

---

### 18250

**MD number**: MM_CHAN_HASH_TABLE_SIZE  
**Hash table size for channel-specific data**

| Default value: 7 | Min. input limit: 7 | Max. input limit: 193 |

**Changes effective after Power On**: Protection level: 0  
**Unit**: prime number  
**Data type**: DWORD  
**Applies from SW version**: 1.1

**Significance**:  
Defines the size for channel-specific names. The value entered must be a prime number. The setting allows the optimization of the interpreter execution time (smaller value = larger execution time) and memory requirements (smaller value = less dynamic memory). A larger table requires a smaller number of decoding operations for decoding the variables and consequently a shorter interpreter execution time. The value of this machine data affects the amount of dynamic memory required. The required memory for each channel in bytes is equal to the value entered multiplied by 68.

**Special cases, errors, .....**: The backup data are lost if this machine data is altered!

**Note**: This machine data is assigned internally by the control and must not be altered by the user.
### 4.1 General machine data

#### 18260 MM_NCK_HASH_TABLE_SIZE

<table>
<thead>
<tr>
<th>MD number</th>
<th>Data type: DWORD</th>
<th>Description</th>
<th>Default value</th>
<th>Min. input limit</th>
<th>Max. input limit</th>
<th>Changes effective after Power On</th>
<th>Protection level</th>
<th>Unit: prime number</th>
<th>Applies from SW version:</th>
<th>1.1</th>
</tr>
</thead>
</table>

**Significance:**
- Defines the size for NCK-specific names.
- The value entered must be a prime number.
- The setting allows the optimization of:
  - the interpreter execution time (smaller value = larger execution time)
  - memory requirements (smaller value = less dynamic memory).

A larger table requires a smaller number of decoding operations for decoding the variables and consequently a shorter interpreter execution time. The value of this machine data affects the amount of dynamic memory required. The required memory for each channel in bytes is equal to the value entered multiplied by 68.

**Special cases, errors, ......**
- The backup data are lost if this machine data is altered!

**Note**
- This machine data is assigned internally by the control and must not be altered by the user.

---

#### 18270 MM_NUM_SUBDIR_PER_DIR

<table>
<thead>
<tr>
<th>MD number</th>
<th>Data type: DWORD</th>
<th>Description</th>
<th>Default value</th>
<th>Min. input limit</th>
<th>Max. input limit</th>
<th>Changes effective after Power On</th>
<th>Protection level</th>
<th>Unit: --</th>
<th>Applies from SW version:</th>
<th>1.1</th>
</tr>
</thead>
</table>

**Significance:**
- Defines the maximum number of subdirectories that a directory in the passive file system can have.
- The number of directories is limited by MD 18310: MM_NUM_DIR_IN_FILESYSTEM (no. of directories in passive file system).
- The memory requirement is contained in the memory for the number of files per directory (see MD 18260: MM_NUM_FILES_PER_DIR).

**Related to ....**
- MD 18310: MM_NUM_DIR_IN_FILESYSTEM (no. of directories in passive file system)

---

#### 18280 MM_NUM_FILES_PER_DIR

<table>
<thead>
<tr>
<th>MD number</th>
<th>Data type: DWORD</th>
<th>Description</th>
<th>Default value</th>
<th>Min. input limit</th>
<th>Max. input limit</th>
<th>Changes effective after Power On</th>
<th>Protection level</th>
<th>Unit:</th>
<th>Applies from SW version:</th>
<th>1.1</th>
</tr>
</thead>
</table>

**Significance:**
- Specifies the maximum number of files which can be created in a directory or subdirectory.
- The total number of files is limited by MD 18320: MM_NUM_FILES_IN_FILESYSTEM (no. of files in passive file system).
- The memory in bytes required for the management of files in the directory is the value entered multiplied by 40.
- The highest value of MD 18280: MM_NUM_FILES_PER_DIR (number of files per directory) and MD 18270: MM_NUM_SUBDIR_PER_DIR (no. of subdirectories) must be entered as the MD setting.
- The memory required to manage files in the passive file system is reserved by MD 18320: MM_NUM_FILES_IN_FILESYSTEM.

**Special cases, errors, ......**
- The backup data are lost if this machine data is altered.

**Note**
- An alteration of the MD has an effect on directories created after this. This means that if the number of files in an existing directory is to be altered, the existing directory must first be deleted and then a new directory must be made (but only after having first saved the files)!

**Related to ....**
- MD 18320: MM_NUM_FILES_IN_FILESYSTEM (number of files in passive file system)
### 4.1 General machine data

#### 18290  MM_FILE_HASH_TABLE_SIZE

<table>
<thead>
<tr>
<th>MD number</th>
<th>Significance:</th>
<th>Default value:</th>
<th>Min. input limit:</th>
<th>Max. input limit:</th>
</tr>
</thead>
<tbody>
<tr>
<td>NCU 570: 19</td>

Changes effective after Power On: Protection level: 0

Data type: DWORD  Applies from SW version: 1.1

Unit: prime number

Significance: Defines the size of the hash table for the subdirectories of a directory. The value entered must be a prime number. The setting allows the optimization of

- the interpreter execution time (smaller value = larger execution time)
- memory requirements (smaller value = less dynamic memory).

The value of this machine data affects the amount of static memory required for the management of directories, see MD 18310: MM_NUM_DIR_IN_FILESYSTEM (no. of directories in passive file system)

Special cases, errors, ...... The backup data are lost if this machine data is altered!

Note: This machine data is assigned internally by the control and must not be altered by the user.
### 18310 MM_NUM_DIR_IN_FILESYSTEM

**MD number:** 18310  
**Description:** Number of directories in passive file system

- **Default value:**  
  - NCU 570: 32  
  - NCU 571: 30  
  - NCU 572: 30  
  - NCU 573: 30

- **Min. input limit:**  
  - NCU 570: 24  
  - NCU 571: 30  
  - NCU 572: 30  
  - NCU 573: 30

- **Max. input limit:**  
  - NCU 570: 64  
  - NCU 571: 150  
  - NCU 572: 150  
  - NCU 573: 150

- **Changes effective after Power On:** Yes

- **Protection level:** 2

- **Data type:** DWORD

- **Significance:** This machine data limits the number of directories in the passive file system and can be used to reserve memory in the SRAM for the management of the directories. The directories and subdirectories of the passive file system set up by the system are included in this machine data. The memory required for the management of the directories can be calculated as follows:

  \[
  \text{Memory required} = a \times (440 + 28 \times (b + c)) \text{ bytes}
  \]

  where:

  - \(a\) = Input value of MD 18310: **MM_NUM_DIR_IN_FILESYSTEM** (no. of directories in passive file system)
  - \(b\) = Input value of MD 19300: **MM_DIR_HASH_TABLE_SIZE** (HASH table size for subdirectories)
  - \(c\) = Input value of MD 18290: **MM_FILE_HASH_TABLE_SIZE** (hash table size for the files of a directory)

- **Special cases, errors:** The backup data are lost if this machine data is altered.

- **Related to:** MD 18270: **MM_NUM_SUBDIR_PER_DIR** (no. of subdirectories)

### 18320 MM_NUM_FILES_IN_FILESYSTEM

**MD number:** 18320  
**Description:** Number of files in passive file system

- **Default value:**  
  - NCU 570: 64  
  - NCU 571: 128  
  - NCU 572: 100  
  - NCU 573: 100

- **Min. input limit:**  
  - NCU 570: 24  
  - NCU 571: 24  
  - NCU 572: 64  
  - NCU 573: 64

- **Max. input limit:**  
  - NCU 570: 128  
  - NCU 571: 512  
  - NCU 572: 512  
  - NCU 573: 512

- **Changes effective after Power On:** Yes

- **Protection level:** 2

- **Data type:** DWORD

- **Significance:** Defines the number of files available in the part program memory. This machine data is used to reserve memory in SRAM – approximately 320 bytes – for file management. Each file created requires a minimum of one Kbytes of memory for the file code. If the one KB limit for the file code is exceeded another Kbytes is reserved for the file.

- **Special cases, errors:** The backup data are lost if this machine data is altered.

- **Related to:** MD 18280: **MM_NUM_FILES_PER_DIR** (number of files in directories)

### 18330 MM_CHAR_LENGTH_OF_BLOCK

**MD number:** 18330  
**Description:** Maximum length of an NC block

- **Default value:** 256

- **Changes effective after Power On:** Yes

- **Protection level:** 0

- **Data type:** DWORD

- **Significance:** None

- **MD irrelevant for:** The functionality is not available with SW 2.
### 18340

<table>
<thead>
<tr>
<th>MD number</th>
<th>MM_NUM_CEC_NAMES</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Number of LEC tables</td>
</tr>
</tbody>
</table>

- **Default value:** 4
- **Min. input limit:** 4
- **Max. input limit:** 4
- **Changes effective after Power On:**
- **Protection level:** 0
- **Unit:** –
- **Data type:** DWORD
- **Significance:** MM_NUM_CEC_NAMES cannot be altered!
- **References:**

  - In the NC program, the Compensation table is assigned to one of the names.
  - The Compensation values are stored in the backed-up memory, their number can be defined in MD 38000: MM_ENC_COMP_MAX_POINTS (no. of interpolation points with interpolation compensation). The memory required is approximately 1 KB in this software version.

- **Special cases:**

  - Software Version 2, the names for the inclusion of CEC data are permanently assigned. The backup data are lost if this machine data is altered.

### 18342

<table>
<thead>
<tr>
<th>MD number</th>
<th>MM_CEC_MAX_POINTS</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Maximum table size for beam sag compensation</td>
</tr>
</tbody>
</table>

- **Default value:** 0
- **Min. input limit:** 0
- **Max. input limit:** 2000
- **Changes effective after Power On:**
- **Protection level:** 2
- **Unit:** –
- **Data type:** DWORD
- **Significance:**

  - Maximum table size for interpolative compensation between axes.
  - When MM_CEC_MAX_POINTS = 0, no memory is set up for the table. The sag compensation function cannot then be used.

- **Special cases:**

  - A change in this machine data causes reconfiguration of the buffered memory area.

### 18350

<table>
<thead>
<tr>
<th>MD number</th>
<th>MM_USER_FILE_MEM_MINIMUM</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Minimum part program memory</td>
</tr>
</tbody>
</table>

- **Default value:** 20
- **Min. input limit:** 20
- **Max. input limit:** 100
- **Changes effective after Power On:**
- **Protection level:** 1
- **Unit:** KB
- **Data type:** DWORD
- **Significance:**

  - Defines the minimum backup memory area remaining for the files of the passive file system. The settable value depends on the hardware and software configurations (SRAM memory allocation) and on MD 18230: MM_USER_MEM_BUFFERED (SRAM user memory). When the SRAM memory is allocated, the remaining memory is allocated to the files of the passive file system. In order to ensure that the file system can operate, the memory space specified in MM_USER_FILE_MEM_MINIMUM must be available to the memory. If this is not assured, the memory is allocated with the default data on the control and all the data stored in the SRAM by the user is lost. Alarm 6000 "Memory allocation with standard machine data" is also output.
  - The available part program memory capacity is displayed in MD 18060: INFO_FREE_MEM_STATIC (display of free static memory).

- **Special cases:**

  - The backup data are lost if this machine data is altered and the remaining memory is smaller than the value in MM_USER_FILE_MEM_MINIMUM.

</table>

<table>
<thead>
<tr>
<th>Data type:</th>
<th>Applies from SW version:</th>
</tr>
</thead>
<tbody>
<tr>
<td>BYTE</td>
<td>1:1</td>
</tr>
</tbody>
</table>

**Significance:**
The machine data defines the percentage of the IPO buffer above which data in the REORG LOG memory can be released in stages, if the block preparation has been interrupted due to an overflow of the REORG LOG data memory. The released data are no longer available to the REORG function (References: /FB/, K1, "Mode Groups, Channels, Program Operation Mode"). A consequence of this status is that a further REORG command is cancelled with an error message. If the status of “non-reorganizability” occurs, warning 15110 is output. The output of the warning can be suppressed by enabling the highest significant bit. The bit is set by adding the value 128 to the input value in REORG_LOG_LIMIT. In addition to the instructions of the NC blocks, the size of the IPO buffer and the REORG data memory also affect the frequency of data release.

**Related to ....**
- MD 28000: MM_REORG_LOG_FILE_MEM (memory size for REORG)
- MD 28060: MM_IPO_BUFFER_SIZE (no. of blocks in the IPO buffer)

</tbody>
</table>

<table>
<thead>
<tr>
<th>Data type:</th>
<th>Applies from SW version:</th>
</tr>
</thead>
<tbody>
<tr>
<td>DWORD</td>
<td>1:1</td>
</tr>
</tbody>
</table>

**Significance:**
Defines the size of dynamic memory for the REORG LOG data. The size of the memory determines the amount of data available for the REORG function.

**References**
-/FB/, K1, "Mode Groups, Channels, Program Operation Mode"
### MM_NUM_REORG_LUD_MODULES

<table>
<thead>
<tr>
<th>Default value</th>
<th>Min. input limit</th>
<th>Max. input limit</th>
<th>Protection level</th>
<th>Data type</th>
<th>Applies from SW version</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>0</td>
<td>100</td>
<td>2</td>
<td>DWORD</td>
<td>1.1</td>
</tr>
</tbody>
</table>

#### Significance:
Defines the number of additional LUD modules provided for the REORG function (see Description of Functions, Mode Groups, Channels, Program Operation Mode (K1)). If the REORG function is not used, this value can be 0. The CNC always opens 12 LUD modules: 8 for NC programs and 4 for asynchronous subprograms. One LUD module is required for each NC program or asynchronous subprogram containing a definition of a local variable. It may be necessary to increase this value for REORG if a larger IPO buffer is provided and a large number of short NC programs containing LUD variable definitions are active (the NC blocks of the program are stored in prepared format in the IPO buffer. One LUD module is required for each of these programs. The capacity of the reserved memory is affected by the number of LUDs per NC program and their individual memory requirements.

The LUD modules are stored in dynamic memory. The memory required for managing the modules for local user variables with REORG can be calculated as follows:

\[
\text{Memory} = a \times (200 + b \times 160) \text{ bytes}
\]

- \(a\) = total number of LUD modules = 8 + 4 + value in MD: MM_NUM_REORG_LUD_MODULES
- \(b\) = Input value of MD 18240: MM_LUD_HASH_TABLE_SIZE (hash table size for user variables)

The size of the LUD modules depends on the number of active LUDs and their data types. The memory for LUD modules is limited by MD 28000: MM_REORG_LOG_FILE_MEM (memory size for REORG).

#### Application
Example:
A main program consisting of 4 NC blocks is started:
- A LUD variable is defined in the first block.
- A subprogram, nested up to 8 levels, is called in each of the second and third blocks.
- The fourth block terminates the program.

Each subprogram comprises 3 NC blocks:
- A LUD variable is defined in the first block.
- A subprogram call to the next program level is executed in the second block.
- The third block terminates the subprogram.

Instead of a subprogram call, the subprogram in the last program level contains a different command, such as a traversing movement. This makes a total of 15 programs with 46 NC blocks which can all be stored in prepared format in the IPO buffer. Since the REORG function requires all the data of the 46 blocks, LUD modules for 3 programs are missing. A value of 3 for the additionally required LUD data blocks must be entered in MM_NUM_REORG_LUD_MODULES for the example given.
### 28020 - MM_NUM_LUD_NAMES_TOTAL

<table>
<thead>
<tr>
<th>MD number</th>
<th>MM_NUM_LUD_NAMES_TOTAL</th>

<tr>
<td>Max. input limit:</td>
<td>100</td>
</tr>
<tr>
<td>Changes effective after Power On</td>
<td>Protection level: 2</td>
</tr>
<tr>
<td>Data type:</td>
<td>DWORD</td>
</tr>
<tr>
<td>Significance:</td>
<td>This MD defines the amount of memory space available for LUD variables. The number of available LUDs is exhausted when one of the limit values in either MD 28020: MM_NUM_LUD_NAMES_TOTAL or MM_LUD_VALUES_MEM is reached. The memory defined here is subdivided into (MM_LUD_VALUES_MEM * 1024) / MM_MAX_SIZE_OF_LUD_VALUE blocks and allocated to part programs which request memory. Each part program which contains at least one definition of LUD variables or which has call parameters uses at least one such block. It should be remembered that several part programs can be open at once and thus use memory on the NCK. The number depends on the type of programming, the program length and the size of the internal NCK block memory upwards of (MM_IPO_BUFFER_SIZE, MM_NUM_BLOCKS_IN_PREP).</td>
</tr>

<td>Min. input limit: 100</td>
</tr>
</tbody>
</table>

- Changes effective after Power On: True
- Protection level: 0
- Unit: KB
- Data type: DWORD
- Applies from SW version: 1.1

**Significance:** None. This MD no longer exists in SW 2.
### 4.3 Axis-specific machine data

#### 38000 MM_ENC_COMP_MAX_POINTS
- **MD number**: 38000
- **Number of interpolation points for interpolative compensation**
- **Default value**: 0
- **Min. input limit**: 0
- **Max. input limit**: 5000
- **Changes effective after Power On**: 
- **Protection level**: 2
- **Data type**: DWORD
- **Applies from SW version**: 1.1
- **Significance**: Defines the number of lead screw compensation values per encoder for the axis. This value reserves 8 bytes of backup user memory for each compensation value. If more memory for compensation values is required than available in the SRAM, the control outputs alarm 6000 “Memory allocation with standard machine data” on power-up.
- **Special cases, errors**: The backup data are lost if this machine data is altered!
- **References**: /FB/, K3, "Compensations"

#### 38010 MM_QEC_MAX_POINTS
- **MD number**: 38010
- **Number of values for quadrant error compensation**
- **Default value**: 0
- **Min. input limit**: 0
- **Max. input limit**: 1040
- **Changes effective after Power On**: 
- **Protection level**: 2
- **Data type**: DWORD
- **Applies from SW version**: 2
- **Significance**: Number of possible values for quadrant error compensation with neural network (option). With a setting of "0": The quadrant error compensation function cannot be activated, no memory is set up for the function.
- **Special cases, errors**: The backup data are lost if this machine data is altered!
- **References**: /IAD/, “SINUMERIK 840D Installation and Start-up Guide” /FB/, K3, "Compensations"

Brief Description

Indexing axes on machine tools

In certain applications, the axis is only required to approach specific grid points (e.g. location numbers). It is necessary to approach the defined grid points (called indexes) both in automatic and set-up modes. These axes are known as “indexing axes”. The positions defined on the indexing axes are known as “coded positions” or “index positions”. In SW 4.3 and higher, special functions are available for equidistant indexing on linear and rotary axes and for the Hirth tooth system.

Applications

Indexing axes are used predominantly in connection with specific types of tool magazine such as tool turrets, tool chain magazines or tool cartridge magazines. The coded positions refer to the individual locations of the tools in the magazines. During a tool change, the magazine is positioned at the location containing the tool to be loaded.
Detailed Description

2.1 Traversing indexing axes

General

Indexing axes can be traversed manually in the setup mode types JOG and INC, from a part program with special instructions for “Coded positions” and by the PLC. When the indexing position has been reached, the “indexing axis in position” interface signal (DB31–61, DBX76.6) is output to the PLC.

Hirth indexing axes cannot be traversed in JOG mode before reference point approach.

2.1.1 Traversing indexing axes in manual JOG mode

Reference point approach

An indexing axis approaches the reference point in the same way as other axes. It is not necessary for the reference point to match an indexing position. Only when the reference point has been reached (IS “Referenced/synchronized 1 or 2” (DB31–61, DBX60.4 or 5) = “1”) does the indexing axis approach only indexing positions in JOG mode with conventional and incremental traversing.

Exception: when traversing with the handwheel, no indexing positions are approached.

If the axis is not referenced (IS “Referenced/synchronized 1 or 2” = “0”), the indexing positions are ignored when the axis is traversed in manual jog mode!
### Continuous traversal in JOG

- **Jog mode (SD: JOG_CONT_MODE_LEVELTRIGGRD = "1")**: Pressing a “+” or “−” traversing key causes the indexing axis to move in the same way as with conventional JOG traversing. When the traversing key is released, the indexing axis traverses to the next indexing position in the direction of traversing.

- **Continuous mode (SD: JOG_CONT_MODE_LEVELTRIGGRD = "0")**: Pressing the traversing key briefly (first rising signal edge) starts the traversing movement of the indexing axis in the desired direction. Traversing continues when the traversing key is released. When the traversing key is pressed again (second rising signal edge), the indexing axis traverses to the next indexing position in the direction of traversing.

Indexing axes are generally traversed in JOG mode (standard setting). Continuous mode plays a less important role.

If the operator changes the direction of traversing before the indexing position has been reached, the indexing axis is positioned on the next indexing position in the direction of traversing. The traversing movement must be started in the opposite direction.

For further information on continuous traversing in jog or continuous mode, please see: **References**: /FB/, H1 “Manual and Handwheel Travel”

### Incremental traversal in JOG (INC)

Irrespective of the increment value currently set (INC1; ... .INCvar), the indexing axis **always traverses incrementally by 1 indexing position** in the selected direction when a “+” or “−” traversing key is pressed.

In jog mode, the traversing movement is interrupted when the traversing key is released. The indexing position can be approached by pressing the traversing key again.

In continuous mode, the traversing movement is aborted when the traversing key is pressed again. The indexing axis is, in this case, not located on the indexing position.

### Between two indexing positions

If an indexing axis is situated between 2 indexing positions, then it approaches the next-higher indexing position when the “+” traversing key is pressed in JOG-INC mode. Similarly, pressing the “−” traversing key causes the next lower indexing position to be approached.

### Handwheel traversal

When the indexing axis is traversed by means of the handwheel in JOG mode, the indexing positions **are ignored**. Rotating the handwheel traverses the indexing axis to any position in mm, inches or degrees, according to the standard unit of measurement.

The PLC user program can disable the handwheel for traversing the indexing axis.

### Signal from PLC “Indexing axis in position”

When the indexing axis is traversed in JOG mode, the signal “Indexing axis in position” (DB31–61, DBX76.6) is output at the PLC interface to indicate that an indexing position has been reached. The indexing axis must have been referenced (IS “Referenced/synchronized 1 or 2” = “1”).
Alarms in JOG mode

If the indexing axis leaves the traversing range defined in the indexing position table (see 2.2) when traversing in JOG mode, alarm 20054 “wrong index for indexing axis in JOG” is output.

Revolutional feedrate

In JOG mode the behavior of the axis/spindle also depends on the setting of setting data JOG_REV_IS_ACTIVE (revolutional feedrate when JOG active).

- If this setting data is active, an axis/spindle is always moved with revolutional feedrate MD JOG_REV_VELO (revolutional feedrate with JOG) or MD JOG_REV_VELO_RAPID (revolutional feedrate with JOG with rapid traverse overlay) depending on the master spindle.

- If the setting data is not active, the behavior of the axis/spindle depends on the setting data ASSIGN_FEED_PER_REV_SOURCE (revolutional feedrate for positioning axes/spindles).

- If the setting data is not active, the behavior of a geometry axis on which a frame with rotation is effective depends on the channel-specific setting data JOG_FEED_PER_REV_SOURCE. (In the operating mode JOG, revolutional feedrate for geometry axes on which a frame with rotation is effective).

2.1.2 Traversing indexing axes in AUTOMATIC modes

Traversing to selected positions

An axis defined as an indexing axis can be made to approach any selected position from the NC part program in AUTOMATIC mode. This includes positions between the defined indexing positions. These positions are programmed, in the usual way, in the unit of measurement (mm/inches or degrees) for the axis. The general programming instructions used for this purpose (G90, G91, AC, IC, etc.) are described in the Programming Guide.

Traversing to “Coded Positions”

Special instructions can also be programmed in the part program:

- CAC Approach absolute coded position
- CACP Approach absolute coded position in positive direction
- CACN Approach absolute coded position in negative direction
- CIC Approach incremental coded position
- CDC Approach coded position along direct (shortest) path

to traverse in the specified manner.

With absolute positioning, the indexing position to be approached is programmed, and with incremental positioning, the number of indexes to be traversed in the “+” or “−” direction is programmed.
On rotary axes, the indexing position can be approached directly across the shortest path (CDC) or with a defined direction of rotation (CACP, CACN). Please refer to Section 2.3 for further information on the special programming instructions for indexing axes.

When an indexing axis is traversing in AUTOMATIC mode, interface signal “Indexing axis in position” is set only if special instructions for approaching “Coded positions” (CAC, CIC, etc.) have been used. In all other cases, the interface signal remains set to “0”, even if a position approached with G90 or G91 exactly matches an indexing position.

SW 4.3 and higher:
If the “Exact stop fine” window is reached and the indexing axis is positioned on an indexing position, the signal is enabled regardless of how the indexing position was reached.

### 2.1.3 Traversing of indexing axes by PLC

**Traversal by PLC**

Indexing axes can also be traversed from the PLC user program. There are various methods:

- With concurrent positioning axes
  - In this case, the indexing position to be approached can be specified by the PLC.
  
  **References:** /FB/, P2 “Positioning Axes”

- With asynchronous subprograms (ASUP)
  - **References:** /FB/, K1 “Mode Groups, Channels, Program Operation”
2.2 Parameterization of indexing axes

Definition of the indexing axis

An axis (linear or rotary axis) can be defined as an indexing axis with the aid of the axial machine data INDEX_AX_ASSIGN_POS_TAB. The number of the indexing position table (1 or 2) must be entered in the machine data.

Several axes can be assigned to an indexing position table on the condition that they are all of the same type (linear axis, rotary axis, modulo 360° function). If they are not, alarm 4080 “Incorrect configuration of indexing axis in MD [name]” is output during power-up.

Indexing position tables

The axis positions (in mm or degrees) assigned to the indexes must be stored for each indexing axis in the form of a table in machine data. Any value can be entered for the distance between the individual indexing positions.

The following should be noted when entering the indexing positions:

Number of tables

Up to 2 indexing position tables are permitted:

- MD 10910: INDEX_AX_POS_TAB_1 [n]
- MD 10930: INDEX_AX_POS_TAB_2 [n]

Number of entries for each table

Up to 60 positions can be entered in each indexing position table \([n = 0 \ldots 59]\).

The actual number of entries used must be defined with machine data

- MD 10900: INDEX_AX_LENGTH_POS_TAB_1 bzw.
- MD 10920: INDEX_AX_LENGTH_POS_TAB_2

for table 1 and/or 2.

All positions entered in the table which are higher than the number defined in the machine data are inactive.

Inch/metric switchover

Up to SW 5, when inputting the rotary axis indexing position on an inch machine (MD 10240: SCALING_SYSTEM_IS_METRIC=0), the value still has to be divided by 25.4 despite the input in degrees.

From SW 5 and MD 10260: CONVERT_SCALING_SYSTEM=1 (see /G2/) the indexing positions no longer refer to the basic system that is set but to the measuring system set in MD 10270: POS_TAB_SCALING_SYSTEM.

- MD 10270: POS_TAB_SCALING_SYSTEM=0: metric
- MD 10270: POS_TAB_SCALING_SYSTEM=1: inch
2.3 Programming of indexing axes

Note

MD 10270 defines the measuring system for position specifications for the following machine data:

- MD 10900: INDEX_AX_POS_TAB_1
- MD 10920: INDEX_AX_POS_TAB_2

MD 10270 also affects SD 41500 to SD 41507 (see /N3/).

Entry format

- The indexing positions should be entered in the table in ascending order (starting with the negative to the positive traversing range) with no gaps between the entries. Consecutive position values cannot be identical.

- The axis positions should be entered in the standard coordinate system.

If the indexing axis is defined as a rotary axis with modulo 360° (MD: IS_ROT_AX = “1” and MD: ROT_IS_MODULO = “1”), the following points should also be observed with respect to indexing positions:

- Indexing positions may be programmed in the range from 0° ≤ Pos < 360°. Positions outside this range generate alarm 4080 on power-up.

- Since the indexing axis is defined as a continuously rotating rotary axis, indexing position 1 is approached after the highest valid indexing position in the table has been reached and the axis continues to traverse in the positive direction with INC. Similarly, indexing position 1 is followed by the highest valid indexing position in the negative direction with INC.

2.3 Programming of indexing axes

Note

Please refer to the following documentation for guidelines on the programming of indexing axes.

References: /PA1/, Programming Guide

Coded position

To allow indexing axes to be positioned from the NC part program, special instructions (so-called Coded positions) are provided with which the indexing numbers (e.g. location number) are programmed rather than axis positions in mm or degrees. The following coded position instructions are possible, depending on whether the indexing axis is defined as a linear or rotary axis:

- Indexing axis is a linear axis: CAC(i), CIC(i)
- Indexing axis is a rotary axis: CAC(i), CIC(i), CACP(i), CACN(i), CDC(i)

i = coded position (indexing position)

Value range of i: 0 ... 59; integer; with the exception of CIC positive only
### Programming of Indexing Axes

#### Absolute

**POS[B]=CAC(20)**

Indexing axis B approaches coded position (index) 20 in absolute mode. The direction of traversing depends on the current actual position.

#### Absolute in Positive Direction

**POS[B]=CACP(10)**

Indexing axis B approaches coded position (index) 10 in absolute mode in the positive direction of rotation (only possible with rotary axes).

#### Absolute in Negative Direction

**POS[B]=CACN(10)**

Indexing axis B approaches coded position (index) 10 in absolute mode in the negative direction of rotation (only possible with rotary axes).

#### Direct Absolute

**POS[B]=CDC(50)**

Indexing axis B approaches indexing position 50 directly along the shortest path (only possible with rotary axes).

#### Incremental

**POS[B]=CIC(–4)**

Indexing axis B traverses incrementally by 4 indexing positions in a negative direction from its current position.

**POS[B]=CIC(35)**

Indexing axis B traverses incrementally from the current indexing position across 35 indexing positions in the positive direction. The leading sign defines the direction of approach.

---

**Note**

On modulo rotary axes, the indexing positions are divided in factors of 360 degrees and are approached directly.

---

**Between Indexing Positions**

If an indexing axis is located between 2 indexing positions in automatic mode, the program command `POS[B]=CIC(1)` causes the next higher indexing position to be approached. Similarly, the program instruction `POS[B]=CIC(–1)` causes the next lower indexing position to be approached. With `POS[B]=CIC(0)` the indexing axis does not traverse.

---

**Alarms**

If an indexing position is programmed outside the valid range of the indexing position table, alarm 17510 “Impermissible index for indexing axis” is output. When an indexing position is programmed for an axis, alarm 17500 “Axis is not an indexing axis” if an indexing position table is not assigned to this axis (MD: INDEX_AX_ASSIGN_POS_TAB (axis is an indexing axis)).

---

**FRAMES**

Since the control interprets the positions stored in the indexing position table as programmed positions in mm, inches or degrees, FRAMES are not disabled with indexing axes. FRAMES are not generally required with indexing axes, depending on the application. It is therefore in most cases advisable to suppress FRAMES and zero offsets in the part program for indexing axes.
2.4 Extensions in SW 4.3 and higher, (840D), SW 2.3 (810D)

General information

The extensions include:

- Any number of equidistant index intervals
- Modified action of MD for indexing axes

2.4.1 Equidistant index intervals

Equidistant index intervals can be used for:

- Linear axes
- Modulo rotary axes
- Rotary axes

Distance between indexes

The index distance is determined as follows for equidistant index intervals:

\[
\text{Distance} = \frac{\text{Numerator (MD 30501: $MA_{INDEX\_AX\_NUMERATOR}$)}}{\text{Denominator (MD 30502: $MA_{INDEX\_AX\_DENOMINATOR}$)}}
\]

Linear axis

**MD 30503: $MA_{INDEX\_AX\_OFFSET}$ (1st distance from zero point, positive)**

0

---

Distance (same for all indexes, see above)

**MD 30503: $MA_{INDEX\_AX\_OFFSET}$ (1st distance from zero point, negative)**

0

---

Distance (same for all indexes, see above)
2.4 Extensions in SW 4.3 and higher, (840D), SW 2.3 (810D)

Modulo rotary axis

\[
\text{Index} = \frac{\text{Numerator} \ (\text{MD 30330: $MA\_MODULO\_RANGE})}{\text{Denominator} \ (\text{MD 30502: $MA\_INDEX\_AX\_DENOMINATOR})}
\]

Activation

The functions with equidistant indexing for linear axes and rotary axes or modulo rotary axes are activated by specifying “table number” 3 im MD 30500: $MA\_INDEX\_AX\_ASSIGN\_POS\_TAB[axis].

Hirth tooth system

Introduction

With Hirth tooth systems, positions of rotation on a rotary axis are usually interlocked using a latch or other toothed wheel via a linear axis. The interlock should only be activated when an indexing position has been reached precisely. The distance between the indexing positions is the same (equidistant) across the entire circumference.

Preconditions

The rotary axis must be an indexing axis. The axis must be referenced. See References: /R1/, Reference Point Approach

Activation

MD 30505: $MA\_HIRTH\_IS\_ACTIVE must be set to 1.
MD 30500: $MA\_INDEX\_AX\_ASSIGN\_POS\_TAB must be set to 3 (equidistant indexes).
Effect

- The rotary axis can only approach indexing positions in all modes and operating states.
- In JOG mode, the axis can be traversed conventionally or incrementally. Precondition: The axis is referenced.
- Jogging with the handwheel is not possible. See References: /H1/, Handwheel Travel
- Only "coded positions" can be approached in AUTO, MDA or via ASUPs
- The PLC can only move the axis to indexing positions. An alarm is output on an attempt to approach any other position.

Response of the Hirth axes in particular situations

**STOP/RESET**

On NC STOP and RESET during a traversing movement, the next indexing position is approached before the command is activated.

**EMERGENCY STOP**

After an EMERGENCY STOP, the PLC or the operator must move the indexing axis back to an indexing position in JOG mode before the longitudinal axis can be moved in/down.

**Override = 0 or “Stop axis” signal**

If the axis has already moved away from the previous indexing position when these events occur, the control moves the axis to the next possible indexing position before the response is initiated.

**Delete distance-to-go**

After traversing to the next possible indexing position, the movement is aborted at this position.

**Command axes**

See References: /FBSY/, Synchronized Actions

If MOV = 0 is specified for a moving command axis, the axis continues traversing to the next possible indexing position before stopping.

**Move command**

MOV = 1 Works on indexing axes with and without Hirth tooth system. Move = 0 works the same with both, the next position is approached.

**DELDTG command**

Restrictions

Transformations The axis for which the Hirth tooth system is defined cannot take part in kinematic transformations.

PRESET The axis for which the Hirth tooth system is defined cannot be set to a new value with PRESET.

Revolutional feedrate The axis for which the Hirth tooth system is defined cannot be traversed with revolutionary feedrate.

Path/velocity overlay The axis for which the Hirth tooth system is defined cannot be used with path or velocity overlay.

Frames, ext. ZO, DRF The axis for which the Hirth tooth system is defined does not support frames or interpolation compensation such as external zero offsets, DRF, etc.

Couplings The axis for which the Hirth tooth system is defined cannot be a
- following axis with master value coupling
- coupled-motion axis
- gantry following axis.

See: References: /M3/, Coupled Motion

2.4.2 Modified activation of machine data

In SW 4.3 and higher, only a RESET is required in order to activate the MD below after new values have been assigned to the MDs. (POWER ON was previously required).

- MD 10900: $MN_INDEX_AX_LENGTH_POS_TAB_1
- MD 10920: $MN_INDEX_AX_LENGTH_POS_TAB_2
- MD 10910: $MN_INDEX_AX_POS_TAB_1
- MD 10930: $MN_INDEX_AX_POS_TAB_2
- MD 30500: $MA_INDEX_AX_ASSIGN_POS_TAB

You will find a complete list of MDs for indexing axes in Chapter 4.
2.4.3 Examples of equidistant indexes

**Modulo rotary axis**

$\text{MA\_INDEX\_AX\_DENOMINATOR}[\text{AX4}] = 18$
$\text{MA\_INDEX\_AX\_OFFSET}[\text{AX4}] = 5$
$\text{MA\_INDEX\_AX\_ASSIGN\_POS\_TAB}[\text{AX4}] = 3$
$\text{MA\_IS\_ROT\_AX}[\text{AX4}] = \text{TRUE}$
$\text{MA\_ROT\_IS\_MODULO}[\text{AX4}] = \text{TRUE}$

With the machine data above, axis 4 is defined as a modulo rotary axis and an indexing axis with equidistant positions every 20 degrees starting at 5 degrees. This results in the following indexing positions: 5, 25, 45, 65, 85, 105, 125, 145, 165, 185, 205, 225, 245, 265, 285, 305, 325 and 345 degrees.

**Note**

The $\text{MA\_INDEX\_AX\_DENOMINATOR}[\text{AX4}] = 18$ assignment produces a 20° division because the default for $\text{MA\_MODULO\_RANGE}$ is 360.

**Rotary axis**

$\text{MA\_INDEX\_AX\_NUMERATOR}[\text{AX4}] = 360$
$\text{MA\_INDEX\_AX\_DENOMINATOR}[\text{AX4}] = 18$
$\text{MA\_INDEX\_AX\_OFFSET}[\text{AX4}] = 100$
$\text{MA\_INDEX\_AX\_ASSIGN\_POS\_TAB}[\text{AX4}] = 3$
$\text{MA\_IS\_ROT\_AX}[\text{AX4}] = \text{TRUE}$
$\text{MA\_POS\_LIMIT\_MINUS}[\text{AX1}] = 100$
$\text{MA\_POS\_LIMIT\_PLUS}[\text{AX1}] = 260$

With the machine data above, axis 4 is defined as a rotary axis and an indexing axis with equidistant positions every 20 degrees starting at 100 degrees. This results in the following indexing positions: 100, 120, 140 degrees, etc. Positions less than 100 degrees cannot be approached as indexing positions. It is therefore advisable to place the lower software limit switch in this case. The indexing positions continue until the software limit switch is reached (in this case 260 degrees). The rotary axis can therefore only traverse between 100 and 260 degrees.

**Linear axis**

$\text{MA\_INDEX\_AX\_NUMERATOR}[\text{AX1}] = 10$
$\text{MA\_INDEX\_AX\_DENOMINATOR}[\text{AX1}] = 1$
$\text{MA\_INDEX\_AX\_OFFSET}[\text{AX1}] = -200$
$\text{MA\_INDEX\_AX\_ASSIGN\_POS\_TAB}[\text{AX1}] = 3$
$\text{MA\_IS\_ROT\_AX}[\text{AX1}] = \text{FALSE}$
$\text{MA\_POS\_LIMIT\_MINUS}[\text{AX1}] = -200$
$\text{MA\_POS\_LIMIT\_PLUS}[\text{AX1}] = 200$

With the machine data above, axis 4 is defined as a linear axis and an indexing axis with equidistant positions every 10 mm starting at −200 mm. This results in the following indexing positions: −200, −190, −180 mm etc. These indexing positions continue until the software limit switch is reached (in this case 200 mm).
Hirth tooth system

$\text{MA\_INDEX\_AX\_DENOMINATOR}[\text{AX4}] = 360$

$\text{MA\_INDEX\_AX\_OFFSET}[\text{AX4}] = 0$

$\text{MA\_INDEX\_AX\_ASSIGN\_POS\_TAB}[\text{AX4}] = 3$

$\text{MA\_IS\_ROT\_AX}[\text{AX4}] = \text{TRUE}$

$\text{MA\_ROT\_IS\_MODULO}[\text{AX5}] = \text{TRUE}$

$\text{MA\_HIRTH\_IS\_ACTIVE}[\text{AX4}] = \text{TRUE}$

With the machine data above, axis 4 is defined as a modulo rotary axis and an indexing axis with Hirth tooth system and equidistant positions every 1 degree starting at 0 degrees.
2.5 Starting up indexing axes

Procedure
The procedure for starting up indexing axes is identical to normal NC axes (linear and rotary axes).

Rotary axis
If the indexing axis is defined as a rotary axis (MD: IS_ROT_AX = "1") with modulo 360° conversion (MD: ROT_IS_MODULO = "1"), the indexing positions are traversed with modulo 360°. Only positions within the range from 0° to 359.999° can then be entered in the indexing position table. Otherwise alarm 4080 “Incorrect configuration for indexing axis in MD [Name]” is output. The position display can be set to modulo 360° with the MD: DISPLAY_IS_MODULO = "1".

Special machine data
The following machine data, described in section 4, are also required to be defined:

General machine data
- MD: INDEX_AX_LENGTH_POS_TAB_1 No. of indexing positions used in table 2
- MD: INDEX_AX_LENGTH_POS_TAB_2 No. of indexing positions used in table 2
- MD: INDEX_AX_POS_TAB_1 [n] Indexing position table 1
- MD: INDEX_AX_POS_TAB_2 [n] Indexing position table 2

Axial machine data
- MD: INDEX_AX_ASSIGN_POS_TAB Axis is an indexing axis (assignment of indexing position table 1 or 2, or 3 for equidistant indexing)
- with SW 4.3 and higher:
  - MD: HIRTH_IS_ACTIVE Axis has “Hirth tooth system” property
  - MD: INDEX_AX_NUMERATOR Numerator for equidistant indexing
  - MD: INDEX_AX_DENOMINATOR Denominator for equidistant indexing
  - MD: INDEX_AX_OFFSET Distance of the 1st indexing position from zero
Machine data examples

The assignment of the above machine data is described in the following paragraphs using two examples.

Example of indexing axis as rotary axis

Tool turret with 8 turret locations

The tool turret is defined as a continuously rotating rotary axis. The distances between the 8 turret locations are constant, the first location is at position 0° (see Fig. 2-1).

![Fig. 2-1 Example: Tool turret with 8 locations](image)

Indexing position table

The indexing positions for the tool turret are entered in table 1.

- $\text{SMN_INDEX_AX_POS_TAB} \_1[0] = 0$; 1st indexing position at 0°
- $\text{SMN_INDEX_AX_POS_TAB} \_1[1] = 45$; 2nd indexing position at 45°
- $\text{SMN_INDEX_AX_POS_TAB} \_1[2] = 90$; 3rd indexing position at 90°
- $\text{SMN_INDEX_AX_POS_TAB} \_1[3] = 135$; 4th indexing position at 135°
- $\text{SMN_INDEX_AX_POS_TAB} \_1[4] = 180$; 5th indexing position at 180°
- $\text{SMN_INDEX_AX_POS_TAB} \_1[5] = 225$; 6th indexing position at 225°
- $\text{SMN_INDEX_AX_POS_TAB} \_1[6] = 270$; 7th indexing position at 270°
- $\text{SMN_INDEX_AX_POS_TAB} \_1[7] = 315$; 8th indexing position at 315°

Other machine data

- $\text{SMN_INDEX_AX_LENGTH_POS_TAB} \_1 = 8$; 8 indexing positions in table 1
- $\text{SMA_INDEX_AX_ASSIGN_POS_TAB}[\text{AX5}] = 1$; Axis 5 is defined as an indexing axis, indexing positions in table 1
- $\text{SMA_IS_ROT_AX}[\text{AX5}] = 1$; Axis 5 is a rotary axis
- $\text{SMA_ROT_IS_MODULO}[\text{AX5}] = 1$; Modulo conversion is active
2.5 Starting up indexing axes

Example of indexing axis as linear axis

Workholder with 10 locations (see Fig. 2-2). The distances between the 10 locations vary; the first workholder location is at position −100 mm.

![Diagram showing workholder with 10 locations and indexing positions]

Fig. 2-2 Example: Workholding pallet as an indexing axis

Indexing position table

The indexing positions for the tool turret are entered in table 2.

$MN_INDEX_AX_POS_TAB_2[0] = -100$ ; 1st indexing position at −100
$MN_INDEX_AX_POS_TAB_2[1] = 0$ ; 2nd indexing position at 0
$MN_INDEX_AX_POS_TAB_2[2] = 100$ ; 3rd indexing position at 100
$MN_INDEX_AX_POS_TAB_2[3] = 200$ ; 4th indexing position at 200
$MN_INDEX_AX_POS_TAB_2[4] = 300$ ; 5th indexing position at 300
$MN_INDEX_AX_POS_TAB_2[5] = 500$ ; 6th indexing position at 500
$MN_INDEX_AX_POS_TAB_2[6] = 700$ ; 7th indexing position at 700
$MN_INDEX_AX_POS_TAB_2[7] = 900$ ; 8th indexing position at 900
$MN_INDEX_AX_POS_TAB_2[8] = 1250$ ; 9th indexing position at 1250
$MN_INDEX_AX_POS_TAB_2[9] = 1650$ ; 10th indexing position at 1650

Other machine data

$MN_INDEX_AX_LENGTH_POS_TAB_2 = 10$ ; 10 indexing positions in table 2
$MA_INDEX_AX_ASSIGN_POS_TAB [AX6] = 2$ ; Axis 6 is defined as an indexing axis
; Indexing positions in table 2
2.6 Special features of indexing axes

DRF
An additional incremental zero offset can also be generated for indexing axes in AUTOMATIC mode with the handwheel using the DRF function.

Software limit switches
After the indexing axis has been referenced, the software limit switches are active when the axis is traversed.
When traversing manually in continuous JOG or incremental JOG mode, the indexing axis stops at the last indexing position before the software limit switch.

Reference point approach
An indexing axis will approach indexing positions in JOG mode (continuous or incremental) only after it has reached its reference point (IS “Referenced/synchronized 1 or 2” (DB31–48, DBX60.4 or 5) = “1”). If the axis is not referenced (“referenced/synchronized 1 or 2” interface signal = “0”), the indexing positions are ignored when traversing manually.

Since the axis positions stored in the indexing position tables only correspond to the machine positions when the axis is referenced, an NC start must be disabled for as long as the indexing axis is not referenced.

Position display
Positions on indexing axes are displayed in the units of measurement normally used for the axes (mm, inches or degrees).

Abort through reset
Reset causes the traversing movement on an indexing axis to be aborted and the axis to be stopped. The indexing axis is no longer positioned on an indexing position.

Note
The response of the Hirth tooth system is described in Section 2.4.1.
Notes
### Supplementary Conditions

There are no supplementary conditions stipulated for this Description of Functions.

### Data Descriptions (MD, SD)

#### 4.1 General machine data

<table>
<thead>
<tr>
<th>MD number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>10270</td>
<td>POS_TAB_SCALING_SYSTEM</td>
</tr>
</tbody>
</table>

**Default value:** 0  
**Min. input limit:** 0  
**Max. input limit:** 1  
**Changes effective after RESET:**  
**Protection level:** 2 / 7  
**Unit:** –  
**Applies from SW version:** 5

**Data type:** BYTE

**Significance:** This machine data is for setting the measuring system for position specifications of indexing axis tables and switching points for software cams.

- MD 10270=0: metric
- MD 10270=1: inch

MD 10270 defines the measuring system for position specifications for the following machine data:

- MD 10900: INDEX_AX_POS_TAB_1
- MD 10920: INDEX_AX_POS_TAB_2
- SD 41500: SW_CAM_MINUS_POS_TAB_1
- SD 41501: SW_CAM_PLUS_POS_TAB_1
- SD 41502: SW_CAM_MINUS_POS_TAB_2
- SD 41503: SW_CAM_PLUS_POS_TAB_2
- SD 41504: SW_CAM_MINUS_POS_TAB_3
- SD 41505: SW_CAM_PLUS_POS_TAB_3
- SD 41506: SW_CAM_MINUS_POS_TAB_4
- SD 41507: SW_CAM_PLUS_POS_TAB_4

**Note:** Only effective when MD 10260: CONVERT_SCALING_SYSTEM=1. (see /G2)

**Related to ....**

- see machine and setting data under significance;
- MD 10260: CONVERT_SCALING_SYSTEM
### 10900 INDEX_AX_LENGTH_POS_TAB_1

**MD number**

Number of indexing positions used in Table 1

<table>
<thead>
<tr>
<th>Default value: 0</th>
<th>Min. input limit: 0</th>
<th>Max. input limit: 60</th>
</tr>
</thead>
</table>

**Modification effective after Power On or Reset with SW 4.3 and higher**

**Protection level:** 2 / 7

**Unit:** –

**Data type:** DWORD

**Applies from SW version:** 1.1

**Significance:**

The indexing position table is used to assign the axis positions in the valid unit of measurement (mm, inches or degrees) to the indexing positions \([n]\) on the indexing axis. The number of indexing positions used in table 1 is defined by the MD: `INDEX_AX_LENGTH_POS_TAB_1`. These indexing positions must contain valid values in table 1. Any indexing positions in the table above the number specified in the machine data are ignored. Up to 60 indexing positions (0 to 59) can be entered in the table. Table length = 0 means that the table is not evaluated. If the length is not equal to 0, the table must be assigned to an axis with the MD: `INDEX_AX_ASSIGN_POS_TAB`.

If the indexing axis is defined as a rotary axis (MD: `IS_ROT_AX = "1"`) with modulo 360° (MD: `ROT_IS_MODULO = "1"`), the machine data defines the last indexing position after which the indexing positions begin again at 1 with a further traversing movement in the positive direction.

**Application**

Tool magazines (tool turrets, chain magazines)

**Special cases, errors, ......**

Alarm 17090 "Value violates upper limit" if a value over 60 is entered in the MD: `INDEX_AX_LENGTH_POS_TAB_1`.

**Related to .....**

- MD: `INDEX_AX_ASSIGN_POS_TAB` (axis is an indexing axis)
- MD: `INDEX_AX_POS_TAB_1` (indexing position table 1)
- MD: `IS_ROT_AX` (rotary axis)
- MD: `ROT_IS_MODULO` (modulo conversion for rotary axis)

### 10920 INDEX_AX_LENGTH_POS_TAB_2

**MD number**

Number of indexing positions used in Table 2

<table>
<thead>
<tr>
<th>Default value: 0</th>
<th>Min. input limit: 0</th>
<th>Max. input limit: 60</th>
</tr>
</thead>
</table>

**Modification effective after Power On or Reset with SW 4.3 and higher**

**Protection level:** 2 / 7

**Unit:** –

**Data type:** DWORD

**Applies from SW version:** 1.1

**Significance:**

The indexing position table is used to assign the axis positions in the valid unit of measurement (mm, inches or degrees) to the indexing positions \([n]\) on the indexing axis. The number of indexing positions used in table 2 is defined by the MD: `INDEX_AX_LENGTH_POS_TAB_2`. These indexing positions must contain valid values in table 2. Any indexing positions in the table above the number specified in the machine data are ignored. Up to 60 indexing positions (0 to 59) can be entered in the table. Table length = 0 means that the table is not evaluated. If the length is not equal to 0, the table must be assigned to an axis with the MD: `INDEX_AX_ASSIGN_POS_TAB`.

If the indexing axis is defined as a rotary axis (MD: `IS_ROT_AX = "1"`) with modulo 360° (MD: `ROT_IS_MODULO = "1"`), the machine data defines the last indexing position after which the indexing positions begin again at 1 with a further traversing movement in the positive direction.

**MD irrelevant for ......**

Tool magazines (tool turrets, chain magazines)

**Special cases, errors, ......**

Alarm 17090 "Value violates upper limit" if a value over 60 is entered in the MD: `INDEX_AX_LENGTH_POS_TAB_2`.

**Related to .....**

- MD: `INDEX_AX_ASSIGN_POS_TAB` (axis is an indexing axis)
- MD: `INDEX_AX_POS_TAB_2` (indexing position table 2)
- MD: `IS_ROT_AX` (rotary axis)
- MD: `ROT_IS_MODULO` (modulo conversion for rotary axis)

</tbody>
</table>

**Significance:**

The indexing position table is used to assign the axis positions in the valid unit of measurement (mm, inches or degrees) to the indexing positions [n] on the indexing axis. 

[n] = Index for the entry of the indexing positions in the indexing position table.

**Range:** 0 ≤ n ≤ 59, where 0 is the 1st indexing position and 59 corresponds to the 60th indexing position.

**Note:** Programming with the absolute indexing position (e.g. CAC) starts with indexing position 1. This corresponds to the indexing position with index n = 0 in the table.

The following should be noted when entering the indexing positions:

- Up to 60 different indexing positions can be stored in the table.
- The 1st entry in the table corresponds to indexing position 1; the nth entry corresponds to indexing position n.
- The indexing positions should be entered in the table in ascending order (starting with the negative to the positive traversing range) with no gaps between the entries. Consecutive position values cannot be identical.
- If the indexing axis is defined as a rotary axis (MD: IS_ROT_AX = "1") with modulo 360° (MD: ROT_IS_MODULO = "1") then the position values are limited to a range of 0° ≤ Pos. < 360°.

The number of indexing positions used in the table is defined by the MD:

- INDEX_AX_LENGTH_POS_TAB_1

Entering the value 1 in the MD: INDEX_AX_ASSIGN_POS_TAB assigns indexing position table 1 to the current axis.

**Application**

Tool magazines (tool turrets, chain magazines)

**Special cases, errors, ......**

Alarm 17020 "Illegal array index" if over 60 positions are entered in the table.

**Related to ....**

- MD: INDEX_AX_ASSIGN_POS_TAB (axis is an indexing axis)
- MD: INDEX_AX_LENGTH_POS_TAB_1 (no. of indexing positions used in table 2)
- MD: IS_ROT_AX (rotary axis)
- MD: ROT_IS_MODULO (modulo conversion for rotary axis)
INDEX AX POS TAB_2[n]

## 4.2 Axis-specific machine data

### MD 30500: INDEX AX ASSIGN POS TAB

<table>
<thead>
<tr>
<th>MD number</th>
<th>INDEX AX ASSIGN POS TAB</th>
</tr>
</thead>
<tbody>
<tr>
<td>MD number</td>
<td>Axis is indexing axis</td>
</tr>
</tbody>
</table>

- **Default value:** 0
- **Min. input limit:** 0
- **Max. input limit:** 3
- **Modification effective after Power On or Reset with SW 4.3 and higher**
- **Protection level:** 2 / 7
- **Unit:** --
- **Data type:** BYTE
- **Protection level:** 2 / 7
- **Unit:** --
- **Applies from SW version:** 1.1

### Significance:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The axis is not declared as an indexing axis</td>
</tr>
<tr>
<td>1</td>
<td>The axis is an indexing axis. The indexing positions are stored in table 1 (MD: INDEX AX POS TAB 1)</td>
</tr>
<tr>
<td>2</td>
<td>The axis is an indexing axis. The indexing positions are stored in table 2 (MD: INDEX AX POS TAB 2)</td>
</tr>
<tr>
<td>3</td>
<td>Equidistant indexing with SW 4.3 and higher (840D) and SW 2.3 and higher (810D)</td>
</tr>
<tr>
<td>&gt;3</td>
<td>Alarm 17090 “Value violates upper limit”</td>
</tr>
</tbody>
</table>

### Application

- Tool magazines (tool turrets, chain magazines)
- Several axes can be assigned to an indexing position table on condition that all the axes are of the same type (linear axis, rotary axis, modulo 360° function). If they are not, alarm 4000 is output during power-up.
- Alarm 17500 “Axis is not an indexing axis”
- Alarm 17090 "Value violates upper limit”

### Related to ....

- MD: INDEX AX POS TAB 1 (indexing position table 1)
- MD: INDEX AX LENGTH POS TAB 1 (no. of indexing positions used in table 2)
- MD: INDEX AX POS TAB 2 (indexing position table 2)
- MD: INDEX AX LENGTH POS TAB 2 (no. of indexing positions used in Table 2)

### MD 30501: INDEX AX NUMERATOR

<table>
<thead>
<tr>
<th>MD number</th>
<th>INDEX AX NUMERATOR</th>
</tr>
</thead>
<tbody>
<tr>
<td>MD number</td>
<td>Numerator for indexing axes with equidistant positions</td>
</tr>
</tbody>
</table>

- **Default value:** 0
- **Min. input limit:** >0
- **Max. input limit:** ***
- **Changes effective after RESET**
- **Protection level:** 2 / 7
- **Unit:** mm/inches/degrees
- **Data type:** DOUBLE
- **Protection level:** 2 / 7
- **Unit:** mm/inches/degrees
- **Applies from SW version:** 4.3

### Significance:

- Defines the value of the numerator for calculating the distances between two indexing positions when the positions are equidistant. Modulo axes ignore this value and use $MA MODULO_RANGE instead.
- MD irrelevant for non-equidistant indexes in accordance with tables

### Application

See 2.4

4.3 System variables

Notes
## Signal Descriptions

### 5.1 Axis-specific signals

**DB31, ... DBX76.6**  
Data block

**Indexing axis in position**  
Signal(s) from axis/spindle (NCK —> PLC)

<table>
<thead>
<tr>
<th>Edge evaluation: no</th>
<th>Signal(s) updated: cyclically</th>
<th>Signal(s) valid from SW vers.: 1.1</th>
</tr>
</thead>
</table>

**Signal state 1 or signal transition 0 —> 1**

The signal is influenced according to the “Exact stop fine”. When “Exact stop fine” is achieved, the signal is set. When exiting “Exact stop fine”, the signal is reset again.

- The indexing axis is positioned on an indexing position.
- The indexing axis has been positioned by coded position instructions.

SW 4.3 and higher (840D), SW 2.3 and higher (810D)

If the “Exact stop fine” window is reached and the indexing axis is positioned on an indexing position, the signal is enabled regardless of how the indexing position was reached.

**Signal state 0 or signal transition 1 —> 0**

- The axis is not defined as an indexing axis
- The indexing axis is traversing (IS “Travel command +/-” (DB31, ... DBX64.7/64.6) is active)
- The indexing axis is located at a position which does not correspond to an indexing position.

Examples: In JOG mode after abortion of travel movement, e.g. with RESET
In AUTOMATIC: Indexing axis has, for example, approached a selected position controlled by an AC or DC instruction.

- The indexing axis has not been positioned with instructions for coded positions (CAC, CACP, CACN, CDC, CIC) in automatic mode.
- The “Servo enable” signal for the indexing axis has been cancelled (IS “Servo enable” DB31, ... DBX2.1).

**Signal irrelevant for.....**

Axes that are not defined as indexing axes

(MD 30500: INDEX_AX_ASSIGN_POS_TAB = “0”)

**Application**

Tool magazine: the activation of a gripper for removing a tool from a magazine is triggered when the indexing axis is in position (“indexing axis in position” = 1). This must be programmed in the PLC user program.

**Special cases, errors, .....**

Note:

The axis positions entered in the indexing position table for the individual divisions can be changed through zero offsets (including DRF). The “indexing axis in position” interface signal is then set to 1 when the actual position of the indexing axis matches the value entered in the index table plus the offset. If a DRF is applied to an indexing axis in AUTOMATIC mode, then interface signal “Indexing axis in position” remains active even though the axis is no longer at an indexing position. For exceptions, see 2.4 Hirth tooth system.

**Related to....**

Brief Description

CNC-controlled machine tools are equipped with tool magazines and automatic tool change facility for the complete machining of workpieces.

Procedure

The procedure for changing tools comprises three steps:
- Movement of the tool carrier from the machining position to the tool change position
- Tool change
- Movement of the tool carrier from the tool change position to the new machining position.

Actuation

The tool change can be actuated using a
- T function or an
- M command (preferably M06).

There are two options for tool change:
Immediate change with T number or preparation with T number:
1. Immediate change
   - The T function loads the new tool immediately
   - Typical application: turning machines with tool turrets.
2. Preparation
   - The new tool is prepared for the change on execution of the T function.
   - The M function is used to remove the old tool from the spindle and load the new tool.
   - The M command for tool change can be defined in a machine data.
   - Typical application: milling machines with a tool magazine, in order to bring the new tool into the tool change position without interrupting the machining process.

Tool change point

The selection of the tool change point has a significant effect on the cut-to-cut time. The tool change point is chosen according to the machine tool concept and, in certain cases, according to the current machining task.

The fixed point approach function (G75) can be used to approach fixed positions on a machine axis. These positions are stored in a machine data. Several tool change points can be defined and actuated.

The tool change requires, amongst other things, a tool management system which ensures that the tool to be loaded is available at the tool change position at the right time.
1 Brief description

Notes
2.1 Overview of tool change function

CNC-controlled machine tools are equipped with tool magazines and automatic tool change facility for the complete machining of workpieces.

**Tool changing equipment**

Tool magazines and tool changing equipment are selected according to the machine type.

- **Turning machines:** Tool turret (disc, flat or inclined tool turret); no special equipment required: Tool is changed through rotation of revolver.
- **Milling machines:** Magazines (chain, plate, disc, cassette) with gripper/double gripper for changing.

Since the tool change interrupts machining, the idle times must be minimized.

**Tool change times**

Tool change times are largely determined by the construction of the machine tool.

- Typical tool change times are:
  - 0.1 to 0.2 s for rotation of a tool turret
  - 0.3 to 2 s for a tool change with a gripper when the tool is prepared.

**Cut-to-cut time**

The cut-to-cut time is the period that elapses when a tool is changed between retraction from the interruption point on the contour (from cut) and repositioning on the interruption point (return to cut) with the new tool when the spindle is rotating.

- Typical cut-to-cut times are:
  - 0.3 to 1 s for a turning machine with tool turret
  - 0.5 to 5 s for a milling machine with a tool changer.

**Requirements**

A tool change operation must fulfill the following requirements:

- Short idle times
- Fast search, preparation and return of the tool during machining
- Simple programming of the tool change cycle
Automatic operation of the required axis and gripper movements
- Easy fault recovery.

### 2.2 Sequence of operations

**Tool change sequence**
The tool change operation from cut-to-cut is executed in three steps:
- Movement of the tool carrier from the machining position to the tool change position
- Tool change
- Movement of the tool carrier from the tool change position to the new machining position.
The tool change position depends on the machine concept and is described in more detail in Section 2.4.

**Control of spindle**
The method by which the spindle is controlled during a tool change also depends on the machine design. The various options include systems where
- the spindle continues rotating,
- the spindle is brought to a halt, or
- the spindle is positioned.

### 2.3 Control

**Actuation**
The tool change can be actuated using a
- T function or
- M command (preferably M06).
The selection is made in MD: TOOL_CHANGE_MODE, as follows:

TOOL_CHANGE_MODE = 0
- The new tool is loaded immediately on execution of the T function.
- Typical application: turning machines with tool turrets.

TOOL_CHANGE_MODE = 1
- The new tool is prepared for the change on execution of the T function.
- The M function is used to remove the old tool from the spindle and load the new tool.
- The M command for the tool change is defined in the MD: TOOL_CHANGE_M_CODE. The default setting is 6 for compatibility with DIN 66025.
Typical application: milling machines with a tool magazine, in order to bring the new tool into the tool change position without interrupting the machining process.

Note: If the tool offset number is supplied from the PLC or an MMC tool manager, a “STOPRE” block search stop must be inserted at a suitable point. STOPRE should be avoided, however, when tool radius compensation (G41/G42) or SPLINE interpolation are active, since several blocks are required here in advance for the path calculation.

Further information on M functions which apply to the M06 tool change, such as

- Extended address
- Output time to PLC
- Auxiliary function groups
- Block search
- Overstore

is given in the following documentation:

References: /FB/, S5, “Synchronized Actions”

### 2.4 Tool change point

**Tool change point**

The selection of the tool change point has a significant effect on the cut-to-cut time. The tool change point is chosen according to the machine tool concept and, in certain cases, according to the current machining task.

The fixed point approach function (G75) can be used to approach fixed positions on a machine axis:

```
N20 G75 FP=2 X1=0 Y1=0 Z1=0 LF
```

**Fixed points**

Two fixed positions are stored for each machine axis in MD: FIX_POINT_POS[N]. They are addressed with FP=1 or FP=2. If no value is defined, then FP=1.

Each machine axis which is required to travel to one of these points has to be specified with its machine name and a dummy position (which is not evaluated).

The positions stored in the MD are approached with rapid traverse G0.

In a block with G75, the spindle can be positioned using SPOS and SPOSA.
2.4 Tool change point

Notes
Supplementary Conditions

The tool change requires, amongst other things, a tool management system which ensures that the tool to be loaded is available at the tool change position at the right time.

Data Descriptions (MD, SD)

4.1 Machine data

The machine data required for the tool change are documented in the following sections:

<table>
<thead>
<tr>
<th>MD number</th>
<th>Identifier</th>
<th>Description of Functions</th>
</tr>
</thead>
<tbody>

</table>

Signal Descriptions

No separate signals exist for this Description of Functions.
4.1 Machine data

Notes
Example

The following example shows a typical cut-to-cut sequence of operations for a tool change with a tool changer and a fixed absolute tool change point on a milling machine.

**Machining program**

```
N 970    G0   X=   Y=   Z=   LF ; Retract from contour
N 980    T1   LF ; Tool selection
N 990    W_WECHSEL   LF ; Subprogram call with no Parameter
N 1000   G90   G0   X=   Y=   Z=   M3   S1000   LF; Machining resumed
```

**Subprogram for tool change**

```
PROC   W_WECHSEL   LF
N 10     SPOSA=   S0   LF ; Spindle positioning
N 20     G75   FP=2   X1=0   Y1=0   Z1=0 ; Approach tool change point (see Section 2.4)
N 30     M06   LF ; Change tools
N 40     M17   LF
```

Notes
Brief Description

Contents

This Description of Functions deals with the following subjects:

- Tool offset for grinding operations
- Online tool offsets (continuous dressing)
- Grinding-specific tool monitoring
- Constant grinding wheel peripheral speed (GWPS)

Note

This Description is based on information in

References: /FB/, W1, “Tool Offset”

For information about programming, mode of operation and handling, please refer to

References: /PG/, Programming Guide Fundamentals

________________________________________________________________________
Detailed Description

2.1 Tool offset for grinding operations

2.1.1 Structure of tool data

Grinding tools

Grinding tools (see Sections 2.1.4 and 3) are tools of type 400 to 499.

Tool offset for grinding tools

Apart from edge-specific data, data that are specific to the tool and dressing process are generally also programmed for grinding tools. The data specific to a grinding wheel for the left-hand and right-hand wheel geometry can be stored in D1 or D2 under a T number. If data are required for the dressing geometry, they can be stored, for example, starting at D3 of a T number or in additional edge-specific data (MD 18096 MM_NUM_CC_TOA_PARAM).

Examples:

a)  

<table>
<thead>
<tr>
<th>T number</th>
<th>Grinding wheel</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>D1</th>
<th>Left-hand wheel geometry</th>
</tr>
</thead>
<tbody>
<tr>
<td>D2</td>
<td>Right-hand wheel geometry</td>
</tr>
<tr>
<td>&gt; D3</td>
<td>Additional data</td>
</tr>
</tbody>
</table>

b)  

<table>
<thead>
<tr>
<th>T number</th>
<th>Grinding wheel</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>D1</th>
<th>Left-hand wheel geometry</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>$STC_DP1[t,d]$</td>
</tr>
<tr>
<td></td>
<td>$STC_DP25[t,d]$</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>D2</th>
<th>Right-hand wheel geometry</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>$STC_DP1[t,d]$</td>
</tr>
<tr>
<td></td>
<td>$STC_DP25[t,d]$</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>$TC_DPC1[t,d]$</th>
<th>$TC_DPC10[t,d]$</th>
</tr>
</thead>
<tbody>
<tr>
<td>MD18096 MM_NUM_CC_TOA_PARAM</td>
<td>MD18096 MM_NUM_CC_TOA_PARAM</td>
</tr>
<tr>
<td>$STC_DPC1[t,d]$</td>
<td>$STC_DPC10[t,d]$</td>
</tr>
</tbody>
</table>
All offsets belonging to a grinding wheel and dresser can be combined in the tool edges D1 and D2 for the grinding wheel and, for example, D3 and D4 for the dresser:

- D1: Grinding wheel geometry left
- D2: Grinding wheel geometry right
- D3: Dresser geometry left
- D4: Dresser geometry right

![Diagram of tool offset data and tool-specific grinding data](image)

</tr>
<tr>
<td>25</td>
<td>Technology</td>
<td>Clearance angle</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

Reserved ... means that this tool parameter of the 840D/810D and FM-NC is not used (reserved for expansions).
2.1 Tool offset for grinding operations

Note
The cutting edge data for D1 and D2 of a selected grinding tool can be chained, i.e. if a parameter in D1 or D2 is modified, then the same parameter in D1 or D2 is automatically overwritten with the new value (see tool-specific data $TC_TPC2).

Definition of additional parameters
Additional parameters can be defined via general MD18096: MM_NUM_CC_TOA_PARAM, regardless of the tool type.

Caution
Changes to the MD take effect after POWER ON and will lead to initialization of the memory (backup data up beforehand if necessary!).

No automatic changeover between grinding wheel offset left and right takes place during contour grinding. This changeover must be programmed.
The structure of tool types for grinding tools is as follows:

<table>
<thead>
<tr>
<th>Tool type</th>
<th>X</th>
<th>Y</th>
</tr>
</thead>
<tbody>
<tr>
<td>0:</td>
<td>Without monit. with base dimension for GWPS</td>
<td></td>
</tr>
<tr>
<td>1:</td>
<td>With monit. with base dimension for GWPS</td>
<td></td>
</tr>
<tr>
<td>2:</td>
<td>Without monit. without base dim. for GWPS</td>
<td></td>
</tr>
<tr>
<td>3:</td>
<td>With monit. without base dim. for GWPS</td>
<td></td>
</tr>
<tr>
<td>0:</td>
<td>Surface grinding wheel</td>
<td></td>
</tr>
<tr>
<td>1:</td>
<td>Facing wheel</td>
<td></td>
</tr>
<tr>
<td>9:</td>
<td>Dresser</td>
<td></td>
</tr>
</tbody>
</table>

Fig. 2-2 Structure of tool type for grinding tools, see Fig. 2-1

Note
Channel-specific MD20350: TOOL_GRIND_AUTO_TMON can be set to define whether the monitoring function must already be active when tools with monitoring (i.e. uneven tool types) are selected.

Examples:
This structure can be used to create the following tool types:

- **Type 400**: Surface grinding wheel
- **Type 401**: Surface grinding wheel with monitoring and tool base dimension for GWPS
- **Type 403**: Surface grinding wheel with monitoring/without tool base dimension for GWPS
- **Type 410**: Facing wheel
- **Type 411**: Facing wheel with monitoring with base dimension for GWPS
- **Type 413**: Facing wheel with monitoring without base dimension for GWPS
- **Type 490**: Dresser

### 2.1.3 Tool-specific grinding data

Tool-specific grinding data are available once for every T number (type 400-499). They are automatically set up with every new grinding tool (type 400-499).

Note
Tool-specific grinding data have the same characteristics as a tool edge. This may need to be taken into account when the number of cutting edges is specified in MD18100: MM_NUM_CUTTING_EDGES_IN_TOA.
When all the cutting edges of a tool are deleted, the existing tool-specific grinding data are deleted at the same time.

### Tool-specific grinding data

The parameters are assigned as follows:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Meaning</th>
<th>Data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\text{STC_TPG1}$</td>
<td>Spindle number</td>
<td>Integer</td>
</tr>
<tr>
<td>$\text{STC_TPG2}$</td>
<td>Chaining specification</td>
<td>Integer</td>
</tr>
<tr>
<td>$\text{STC_TPG3}$</td>
<td>Minimum grinding wheel radius</td>
<td>Real</td>
</tr>
<tr>
<td>$\text{STC_TPG4}$</td>
<td>Minimum grinding wheel width</td>
<td>Real</td>
</tr>
<tr>
<td>$\text{STC_TPG5}$</td>
<td>Current grinding wheel width</td>
<td>Real</td>
</tr>
<tr>
<td>$\text{STC_TPG6}$</td>
<td>Maximum speed</td>
<td>Real</td>
</tr>
<tr>
<td>$\text{STC_TPG7}$</td>
<td>Maximum peripheral speed</td>
<td>Real</td>
</tr>
<tr>
<td>$\text{STC_TPG8}$</td>
<td>Angle of inclined grinding wheel</td>
<td>Real</td>
</tr>
<tr>
<td>$\text{STC_TPG9}$</td>
<td>Parameter number for radius calculation</td>
<td>Integer</td>
</tr>
</tbody>
</table>

Additional parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\text{STC_TPC1}$ to $\text{STC_TPC10}$</td>
<td>Real</td>
</tr>
</tbody>
</table>

### Definition of additional parameters

Additional parameters can be defined in general MD: MM\_NUM\_CC\_TDA\_PARAM, regardless of the tool type concerned.

#### Caution

Changes to the MD take effect after POWER ON and will lead to initialization of the memory (back data up beforehand if necessary!).

### Spindle number $\text{STC\_TPG1}$

Number of programmed spindle (e.g. grinding wheel peripheral speed) and spindle to be monitored (e.g. wheel radius and width).

### Chaining rule $\text{STC\_TPG2}$

This parameter is set to define which tool parameters of tool edge 2 (D2) and tool edge 1 (D1) must be chained to one another. When the setpoint of a chained parameter is modified, the value of the parameter with which it is chained is modified automatically.

<table>
<thead>
<tr>
<th>Tool parameter</th>
<th>Meaning</th>
<th>Bit in $\text{STC_TPG2}$</th>
<th>Hex</th>
<th>Dec</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\text{STC_DP1}$</td>

<td>Reserved</td>
<td>33554432</td>
<td>10000000</td>
<td>24</td>
</tr>
</tbody>
</table>

**Example** of parameter chain:

- Lengths 1, 2 and 3 of the geometry, the length wear and the tool base/adapter dimensions of lengths 1, 2 and 3 on a grinding tool (T1 in the example) must be automatically transferred.

- Furthermore, the same tool type applies to tool edges 1 and 2.

**Tool type** $TC_{DP1}$ Bit 0

**Length 1** $TC_{DP3}$ Bit 2

**Length 2** $TC_{DP4}$ Bit 3

**Length 3** $TC_{DP5}$ Bit 4

**Wear**

**Length 1** $TC_{DP12}$ Bit 11

**Length 2** $TC_{DP13}$ Bit 12

**Length 3** $TC_{DP14}$ Bit 13

**Tool base/adapter dimension**

**Length 1** $TC_{DP21}$ Bit 20

**Length 2** $TC_{DP22}$ Bit 21

**Length 3** $TC_{DP23}$ Bit 22

Parameter $TC_{TPG2}$ must therefore be assigned as follows:
### 2.1 Tool offset for grinding operations

#### a) Binary

\[$TC_{TPG2}[1] = 'B111 \ 0000 \ 0011 \ 1000 \ 0001 \ 1101'$(Bit 22 ... bit 0)

#### b) Hexadecimal

\[$TC_{TPG2}[1] = 'H70381D'\]

#### c) Decimal

\[$TC_{TPG2}[1] = 'D7354397'\]

---

**Note**

If the chaining specification is subsequently altered, the values of the two cutting edges are not automatically adjusted, but only after one parameter has been altered.

<table>
<thead>
<tr>
<th>Min. wheel radius and width</th>
<th>The limit values for the grinding wheel radius and width must be entered in this parameter. These parameter values are used to monitor the grinding wheel geometry.</th>
</tr>
</thead>
</table>

**Note**

It must be noted that the minimum grinding wheel radius must be specified in the cartesian coordinate system for an inclined grinding wheel. A signal is output at the PLC interface if the grinding wheel width and radius drop below the minimum limits. The user can use these signals to define his error strategy.

<table>

**Precondition:** A spindle has been declared.
2.1 Tool offset for grinding operations

**Angle of inclined wheel $TC_{TPG8}$**

This parameter specifies the angle of inclination of an inclined wheel in the current plane. It is evaluated for GWPS.

![Fig. 2-3 Machine with inclined infeed axis](image)

**Note**

The tool lengths are not automatically compensated when the angle is altered. The angle must be within the $-90 \leq TC_{TPG8} < +90$ range.

In the case of machines with inclined axes, the same angle must be set for the inclined axis and the inclined grinding wheel. With SW versions NCU 5.1.11/P5 and 4.4.35/P4 and earlier with GWPS for grinding wheel cutting rate and inclined axis, the input value in tool parameter $TC_{TPG8}$ must be set in RAD rather than DEGREE. $TC_{TPG8}$ in RAD = PI/180° angle.

**Parameter number for radius calculation $TC_{TPG9}$**

This parameter can be set to define which offset value for GWPS, tool monitoring ($TC_{TPG3}$) is the first cutting edge of a grinding tool (D1). The number of the grinding spindle can be entered for centerless grinding applications.

**References:** /FB/ S8, Constant Workpiece Speed for Centerless Grinding

<td>$TC_TPG6 [3] = 2000</td>
</tr>
</tbody>
</table>

This system variable allows the tool-specific grinding data for the current tool to be accessed.

- Parameter number (data type: Real)

**Example:**
Parameter 3 ($TPG3[ T No.>])

$P_ATPG[3]=R10

**Note**
- The monitoring data apply to both the left-hand and the right-hand cutting edge of the grinding wheel.
- The tool-specific grinding data take effect when the following are programmed: GWPSON (selection of constant wheel peripheral speed), TMON (selection of tool monitoring function) and CLGON (selection of constant workpiece speed for centerless grinding). To make a changed data effective, GWPSON, TMON or CLGON must be programmed again.
- The length compensations always specify the distances between the tool carrier reference point and the tool tip in the cartesian coordinates (must be noted for inclined grinding wheel).

**2.1.4 Examples of grinding tools**

Tool length compensations for the geometry axes or radius compensation in the plane are assigned on the basis of the current plane.

**Planes**

The following planes and axis assignments are possible (abscissa, ordinate, applicate for 1st, 2nd and 3rd geometry axes):

<table>

Fig. 2-9 Required offset values of a facing wheel with monitoring parameters
2.2 Online tool offset

Application
A grinding operation involves both machining of a workpiece and dressing of the grinding wheel. These processes can be operated in the same channel or in separate channels.

To allow the wheel to be dressed while it is machining a workpiece, the machine must offer a function whereby the reduction in the size of the grinding wheel caused by dressing is compensated on the workpiece.

This type of compensation can be implemented by means of the “Online tool offset” (Continuous Dressing) function (see Chapter 3).

Dressing during machining process
To allow machining to continue while the grinding wheel is being dressed, the reduction in the size of the grinding wheel caused by dressing must be transferred to the current tool in the machining channel as a tool offset that is applied immediately.

This parallel dressing operation can be implemented by means of the Continuous Dressing (parallel dressing), “Online tool offset” function (see Chapter 3).

Note
The online tool offset may only be used for grinding tools.

![Fig. 2-10 Dressing with a dressing roller in parallel to machining](image)
An online tool offset can be activated for every grinding tool in any channel. The online tool offset is generally applied as a length compensation. Like geometry and wear data, lengths are assigned to geometry axes on the basis of the current plane as a function of the tool type.

The grinding spindle monitoring function (see Section 2.3) remains active when an online tool offset is selected.

**Note**
The offset always corrects the wear parameters of the selected length. If the length compensation is identical for several cutting edges, then a chaining specification must be used to ensure that the values for the 2nd cutting edge are automatically corrected as well.

If online offsets are active in the machining channel, then the wear values for the active tool in this channel may not be changed from the machining program or via operator inputs.

Modifications to the radius wear (P15) are not taken into account until the tool is re-selected (<SW4>).

Online offsets are also applied to the constant grinding wheel peripheral speed (GWPS), i.e. the spindle speed is corrected by the corresponding value.

**Commands**
The following commands are provided for online tool offsets:

<table>
<thead>
<tr>
<th>Command</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>FCTDEF</td>
<td>Parameterize function (up to 3rd degree polynomial)</td>
</tr>
<tr>
<td>PUTFTOCF</td>
<td>Write online tool offset continuously</td>
</tr>
<tr>
<td>PUTFTOC</td>
<td>Write online tool offset discretely</td>
</tr>
<tr>
<td>FTOCON</td>
<td>Activation of online tool offset</td>
</tr>
<tr>
<td>FTOCOF</td>
<td>Deactivation of online tool offset</td>
</tr>
</tbody>
</table>

**Note**
Changes to the correction values in the TOA memory do not take effect until T or D is programmed again.

**References:** /PA/, Programming Guide
2.2.1 Write online tool offset: Continuous

Certain dressing strategies (e.g. dressing roller) are characterized by the fact that the grinding wheel radius is continuously (linearly) reduced as the dressing roller is fed in. This strategy requires a linear function between infeed of the dressing roller and writing of the wear value of the respective length.

Function FCTDEF allows 3 independent functions to be defined according to the following syntax:

Parameterize function

The function parameters are set in a separate block according to the following syntax:

\[
\text{FCTDEF}(\text{polynomial no.}, \text{lower limit value}, \text{upper limit value}, \text{coefficient } a_0, \text{coefficient } a_1, \text{coefficient } a_2, \text{coefficient } a_3)
\]

FCTDEF Definition of function
Polynomial no.: Number of function (e.g. 1, 2 or 3)
Lower/upper limit value: Determines value range of function (limit values in input resolutions)
Coefficients \(a_0, a_1, a_2\) Coefficients of polynomial

A polynomial of the 3rd degree is generally defined as follows:

\[
y = a_0 + a_1 \cdot x + a_2 \cdot x^2 + a_3 \cdot x^3
\]

\[y = f(x) = a_0 + a_1 x\]

Fig. 2-11 Straight line equation

Note

FCTDEF must be programmed in a separate NC block.
Example:
Let us assume: Pitch \( a_1 = +1 \)
\( a_2 = 0 \)
\( a_3 = 0 \)
The value of the function must be \( y = 0 \) at the instant of definition and be derived from machine axis \( XA \) (e.g. dresser axis).

\[
\text{FTCDEF}(1, -100, 100, -$AA_IW[XA]$, 1)
\]

Fig. 2-12 Straight line with gradient 1

Write online tool offset continuously

\[
\text{PUTFTOCF( < polynomial no.>, < reference value>, < length1_2_3>, < channel no.>, < spindle no.>)}
\]

\begin{itemize}
  \item **Polynomial no.**: Number of function (1, 2, 3)
  \item **Reference value**: Reference value of function
  \item **Length 1_2_3**: Wear parameter to which correction value is added
  \item **Channel no.**: Channel in which offset must take effect
  \item **Spindle no.**: Spindle to which offset must be applied
\end{itemize}

The online tool offset is activated before the dresser axis movement block.

Example:
\[
\text{FCTDEF (1, -100, 100, -$AA_IW[X], 1)} ; \text{Define function}
\]
\[
\text{PUTFTOCF (1, $AA_IW[X], 1, 2, 1)} ; \text{Write online TO continuously}
\]

Length 1 of tool for spindle 1 in channel 2 is modified as a function of \( X \) axis movement.
Note

The online tool offset for a (geometric) grinding tool that is not active can be activated by specifying the appropriate spindle number.

<table>
<thead>
<tr>
<th>If ...</th>
<th>then ...</th>
</tr>
</thead>
<tbody>
<tr>
<td>no channel no. is specified</td>
<td>the online offset will take effect in this channel</td>
</tr>
<tr>
<td>no spindle no. is specified</td>
<td>the online offset will be applied to the current tool</td>
</tr>
</tbody>
</table>

With SW 3.2 and higher, an online tool offset can be called as a synchronized action.

References: /FB/, S5, “Synchronized Actions”

2.2.2 Activate/deactivate online tool offset

Activation/deactivation of online tool offset

The following commands activate and deactivate the online tool offset in the machining channel (grinding, destination channel):

- **FTOCON** Activation of online tool offset
  The machining channel can process online tool offsets (PUTFTOC) only if the offset is active (FTOCON). Alarm 20204 “PUTFTOC command not allowed” is otherwise output.

- **FTOCOF** Deactivation of online tool offset
  FTOCOF deactivates the online tool offset. The written values remain stored in the appropriate length compensation data.

Online offsets are traversed in the basic coordinate system, i.e. even when the workpiece coordinate system has been rotated, the length compensations always act in parallel to the dimension of the rotated system. The offset is applied regardless of whether or not the axis to be compensated is traversed in the current block.

Note
Command FTOCON must be written to the channel in which the offset must be applied (machining channel for grinding operation).

FTOCOF always corresponds to reset position. PUTFTOC commands are effective only when the part program and command FTOCON are active.
2.2.3 Example of writing online tool offset continuously

Fig. 2-13 Surface grinding machine:

Y: Infeed axis for grinding wheel
V: Infeed axis for dressing roller
X: Oscillation axis, left – right
Plane for tool offset: G19 (Y/Z plane)
Length 1 acts in Z, length 2 in Y, tool type = 401
Machining: Channel 1 with axes Y, X
Dressing: Channel 2 with axis V

Task
After the grinding operation has started at Y100, the grinding wheel must be dressed by 0.05 (in V direction). The dressing amount must be compensated continuously by means of an online offset.

Main machining program in channel 1

... G1 G19 F10 G90 ;Basic setting
   T1 D1 ;Select current tool
   S100 M3 Y100 ;Spindle ON, traverse against starting position
   FTOCON ;Activate online offset
   INIT (2, "/_N_MPF_DIR_/N_ABRICT_MPF", "S") ;Select program in channel 2
   START (2) ;Start program in channel 2
   Y200 ;Traverse against target position
   ... M30
2.2 Online tool offset

Dressing program in channel 2
_N_ABRICHT_MPF

... FCTDEF (1, −1000, 1000, −$AA_IW[V], 1) :Define function
PUTFTOCF (1, $AA_IW[V], 2, 1) ;Write online tool offset continuously
U−0.05 G1 F0.01 G91 ;Infeed movement to dress wheel
...
M30

Note
Axis V operates (dresses) in parallel to Y, i.e. length 2 acts in Y and must therefore be compensated.

2.2.4 Write online tool offset discretely

This command writes an offset value by means of a program command.

PUTFTOC(< value>, < length1_2_3>, < channel no.>, < spindle no.>)
Put Fine Tool-Offset-Compensation
The wear of the specified length (1, 2 or 3) is modified online by the programmed value.

Note
The online tool offset for a (geometric) grinding tool that is not active can be activated by specifying the appropriate spindle number.

<table>
<thead>
<tr>
<th>If ...</th>
<th>then ...</th>
</tr>
</thead>
<tbody>
<tr>
<td>no channel no. is specified</td>
<td>the online offset will take effect in this channel</td>
</tr>
<tr>
<td>no spindle no. is specified</td>
<td>the online offset will be applied to the current tool</td>
</tr>
</tbody>
</table>
2.2.5 Information about online offsets

Response in the case of tool change

- In cases where FTOCON has been active since the last tool or cutting edge change, preprocessing stop with re-synchronization is initiated in the control when a tool is changed.
- Cutting edge changes can be implemented without preprocessing stop.

Machining plane and transformation

- FTOCON can be used only in conjunction with the “inclined axis” transformation.
- It is not possible to change transformations or planes (e.g. G17 to G18) when FTOCON is active, but only in the FTOCOF state.

Resets and operating mode changes

- When online offset is active, NC STOP and program end with M2/M30 are delayed until the amount of compensation has been traversed.
- The online tool offset is immediately deselected in response to NC RESET.
- Online tool offsets can be activated in AUTOMATIC mode and when the program is active.

Supplementary conditions

- The online tool offset is overlaid on the programmed movement of the axis. The programmed limit values (e.g. speed) are taken into account. If a DRF offset and online tool offset are both activated for an axis, the DRF offset has higher priority and is applied first.
- The valid offset is traversed at JOG velocity allowing for the specified maximum acceleration rate.
  Channel-specific MD20610: ADD_MOVE_ACCEL_reserve is taken into account with respect to FTOCON. An acceleration reserve can thus be reserved for the movement which means that the overlaid movement can be executed immediately.
- The valid online offset is deleted on reference point approach with G74.
### 2.3 Online tool radius compensation

#### General
When the longitudinal axis of the tool and the contour are mutually perpendicular, the offset quantity can be applied as a length compensation to one of the three geometry axes (online tool length compensation, see Section 2.2). If this condition is not fulfilled, then the offset quantity can be entered as a real radius compensation value (online tool radius compensation).

#### Enabling of function
The online tool radius compensation function is enabled via MD 20254: SMC_ONLINE_CUTCOM_ENABLE (enable online tool compensation).

#### Activation/deactivation
An online tool radius compensation is activated and deactivated by means of commands FTOCON and FTOCOF (in the same way as an online tool length compensation, see Section 2.2.2).

#### Parameterization
The parameters of the online tool offset are set by means of commands PUTFTOCF (see Section 2.2.1) and PUTFTOC (see Section 2.2.4). Parameter LENGTH 1_2_3 must be supplied as follows for an online tool radius compensation:

Parameter $< \text{length } 1_2_3 > = 4$

Wear parameter in which offset value is added

#### Supplementary conditions
- A tool radius compensation, and thus also an online tool radius compensation, can be activated only when the selected tool has a radius other than zero. This means that machining operations cannot be implemented solely with a tool radius compensation.
- The online offset values should be low in comparison to the original radius to prevent the permitted dynamic tolerance range from being exceeded when the offset is overlaid on the axis movement.
- Application of online tool radius compensation
  
  On grinding and turning tools (types 400–599), the compensation value is applied as a function of the tool point direction, i.e. it acts as a radius compensation when tool radius compensation is active and as a length compensation when tool radius compensation is deactivated in the axes specified by the tool point direction.

  On all other tool types, the compensation value is applied only when tool radius compensation has been activated with G41 or G42. The compensation value is cancelled when tool radius compensation is deactivated with G40.
2.4 Grinding-specific tool monitoring

The tool monitoring function is a combination of geometry and speed monitors and can be activated for any grinding tool (tool type: 400 to 499).

Selection

The monitoring function is selected
- by programming (TMON) in the part program or
- automatically through selection of tool length compensation of a grinding tool with uneven tool type number.

Note
Automatic selection of the monitor must be set via channel-specific MD20350: TOOL_GRIND_AUTO_TMON.

Monitoring function active

The monitor for a grinding tool remains active until it is deselected again by means of program command TMOF.

Note
- Monitoring of one tool is not deselected if the monitoring function is selected for another tool provided the two tools are referred to different spindles.
- One tool and thus also one tool monitor can be active for every spindle at any point in time.
- Activated monitors remain active after a RESET.

2.4.1 Geometry monitoring

The following quantities can be monitored:
- The current grinding wheel radius
- The current grinding wheel width

The current wheel radius is compared to the value stored in parameter $TC_TPG3 (see Section 2.1.3). The current radius is compared to the parameter number of the first edge (D1) of a grinding tool declared in parameter $TC_TPG9.
The current wheel width is generally calculated by the dressing cycle and can be entered in parameter $TC_TPG5$ of a grinding tool. The value entered in this parameter is compared to the value stored in parameter $TC_TPG4$ when the monitoring function is active.

**When does monitoring take place?**

The monitoring function for the grinding wheel radius remains active when an online tool offset is selected.

- When the monitoring function is activated
- When the current radius (online tool offset, wear parameter) or the current width ($TC_TPG5$) is altered.

**Monitor reactions**

If the current grinding wheel radius becomes smaller than the value stored in parameter $TC_TPG3$ or the current grinding wheel width ($TC_TPG5$) drops below the value defined in $TC_TPG4$, the axis/spindle-specific bit DBX83.3 is set to “1” in DB31-48 at the PLC interface. This bit is otherwise set to “0”.

DB31–48, DBX83.3 = 1 ⇒ Geometry monitor has responded
DB31–48, DBX83.3 = 0 ⇒ Geometry monitor has not responded

**Note**

No error reaction is initiated internally in the control system.

### 2.4.2 Speed monitoring

The speed monitor checks the grinding wheel peripheral speed (parameter $TC_TPG7$) as well as the maximum spindle speed (parameter $TC_TPG6$). The monitoring units are:

- Grinding wheel peripheral speed $m \cdot s^{-1}$
- Spindle speed $\text{min}^{-1}$

The monitoring function operates cyclically and is designed to react to the first limit value reached.

**When does monitoring take place?**

Monitoring of the speed for violation of the limit value takes place cyclically, allowing for the spindle speed override.

**When is the speed limit value reset?**

The speed limit value is recalculated

- when the monitoring function is selected,
- when the online offset values (wear parameters) are altered.
Monitor reactions

The system reacts as follows when the speed monitor responds:

- The speed is restricted to the limit value and
- IS "Speed monitoring" (DB31-48, DBX83.6) is output.

DB31–48, DBX83.6 = 1 ⇒ Limit value of speed monitoring reached
DB31–48, DBX83.6 = 0 ⇒ Limit value of speed monitoring not reached

Note

No error reaction is initiated internally in the control system.

2.4.3 Selection/deselection of tool monitoring

The following part program commands are provided for selecting and deselecting the grinding-specific tool monitor of an active or inactive tool:

<table>
<thead>
<tr>
<th>Command</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>TMON</td>
<td>Selection of tool monitoring for the active tool in the channel</td>
</tr>
<tr>
<td>TMOF</td>
<td>Deselection of tool monitoring for the active tool in the channel</td>
</tr>
<tr>
<td>TMON (T number)</td>
<td>Selection of tool monitoring for a non-active tool with T number</td>
</tr>
<tr>
<td>TMOF (T number)</td>
<td>Deselection of tool monitoring for a non-active tool with T number</td>
</tr>
<tr>
<td>TMOF (0)</td>
<td>Deselection of tool monitoring for all tools</td>
</tr>
</tbody>
</table>
### 2.5 Constant grinding wheel peripheral speed (GWPS)

#### What is GWPS?

The grinding wheel peripheral speed is generally programmed for grinding wheels rather than a spindle speed. This is a quantity that is determined by the technological process (e.g. grinding wheel characteristic, material pairing). The speed is then calculated from the programmed value and the current wheel radius.

**Note**  
GWPS can be selected for grinding tools (types 400-499).

#### Speed calculation

The formula for calculating the speed is as follows:

\[
 n \left[ \text{min}^{-1} \right] = \frac{\text{GWPS} \left[ \text{m/s}^{-1} \right] \cdot 60}{2 \pi \cdot R \left[ \text{m} \right]}
\]

**Note**
- The grinding wheel peripheral speed can be programmed and selected for grinding tool types (400 to 499).
- Wear is taken into account in calculating the radius (parameter $\text{TGT}_{\text{TPG9}}$).
- This function also applies to inclined wheels/axes.
- The relevant wear and the tool base dimension (as a function of tool type) are added to the parameter selected by $\text{TGT}_{\text{TPG9}}$. The product is divided by $\cos (\text{TGT}_{\text{TPG8}})$ if parameter $\text{TGT}_{\text{TPG8}}$ (angle of inclined grinding wheel) is positive and by $\sin (\text{TGT}_{\text{TPG8}})$ if it is negative.

#### When is the speed re-calculated?

The speed is re-calculated in response to the following events:
- GWPS programming
- Change in the online offset values (wear parameters)
2.5.1 Selection/deselection and programming of GWPS, system variable

The GWPS is selected and deselected with the following part program commands:

<table>
<thead>
<tr>
<th>Command</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>GWPSON</td>
<td>grinding wheel peripheral speed on</td>
</tr>
<tr>
<td>GWPSOF</td>
<td>grinding wheel peripheral speed off</td>
</tr>
<tr>
<td>GWPSON(T number)</td>
<td>grinding wheel peripheral speed on</td>
</tr>
<tr>
<td>GWPSOF(T number)</td>
<td>grinding wheel peripheral speed off</td>
</tr>
<tr>
<td>S[spindle number] = value</td>
<td>Programming of constant grinding wheel peripheral speed.</td>
</tr>
</tbody>
</table>

Unit of value setting depends on basic system (m/s or ft/s).

References: /PA/, Programming Guide

Note

- Parameter $TC_TPG1 assigns a spindle to the tool. Every following S value for this spindle is interpreted as a grinding wheel peripheral speed when GWPS is active (see above).
- If GWPS must be selected with a new tool for a spindle for which the GWPS function is already active, the active function must be deselected first with GWPSOF before it can be activated again with the new tool (otherwise an alarm is output).
- GWPS can be active simultaneously for several spindles, each with a different grinding tool, in the same channel.
- Selection of GWPS with GWPSON does not automatically result in activation of tool length compensation or of the geometry and speed monitoring functions. When GWPS is deselected, the last speed to be calculated remains valid as the setpoint.

$SP_GWPS[spindle number]$ This system variable can be used in the part program to determine whether GWPS is active for a specific spindle.

TRUE: GWPS programming of spindle active
FALSE: GWPS programming of spindle not active

References: /PG/, Programming Guide
2.5.2 GWPS in all operating modes

General

This function allows the constant grinding wheel peripheral speed (GWPS) function to be selected for a spindle immediately after POWER ON and to ensure that it remains active after an operating mode changeover, RESET or part program end.

The function is activated via MD 35032: $MA_SPIND_FUNC_RESET_MODE (parameterization of GWPS function).

GWPS after POWER ON

A grinding-specific tool is defined via the following MD:

MD 20110: $MC_RESET_MODE_MASK
MD 20120: $MC_TOOL_RESET_VALUE
MD 20130: $MC_CUTTING_EDGE_RESET_VALUE

If

<table>
<thead>
<tr>
<th>If</th>
<th>and</th>
<th>then</th>
</tr>
</thead>
<tbody>
<tr>
<td>MD 35032: $MA_SPIND_FUNC_RESET_MODE is set</td>
<td>the tool is a grinding-specific tool type (400 to 499, MD 20110, 20120, 20130) with reference to a valid spindle (parameter $TC_TPG1),</td>
<td>GWPS is activated for this spindle.</td>
</tr>
</tbody>
</table>

Note:

GWPS is deselected for all other spindles in this channel.

GWPS after RESET/part program end

After a RESET/part program end, GWPS remains active for all spindles for which it was already selected.

If

<table>
<thead>
<tr>
<th>If</th>
<th>and</th>
<th>then</th>
</tr>
</thead>
<tbody>
<tr>
<td>MD 35032: $MA_SPIND_FUNC_RESET_MODE is set</td>
<td>GWPS is active on RESET or part program end,</td>
<td>GWPS remains active for this spindle.</td>
</tr>
<tr>
<td>MD 35032: $MA_SPIND_FUNC_RESET_MODE is not set</td>
<td>GWPS is active on RESET or part program end,</td>
<td>GWPS is deactivated for this spindle.</td>
</tr>
</tbody>
</table>

Note:

GWPS is deselected for all other spindles in this channel.

MD 35040: $MA_SPIND_ACTIVE_AFTER_RESET can be set to determine whether the spindle must continue to rotate at the current speed after RESET.

Programming

The spindle speed can be modified through the input of a grinding wheel peripheral speed. The spindle speed can be modified through

- programming in the part program/overstoring
- programming the grinding wheel peripheral speed through assignment to address “S” in MDA
- spindle speed control via PLC (FC18)

“GWPS active” interface signal

IS “GWPS active” (DB31, ..., DBX84.0) indicates whether or not the GWPS function is active or not.
2.5.3 Example of how to program GWPS

Data of tool T1 (peripheral grinding wheel)

<table>
<thead>
<tr>
<th>Variable</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>$TC_DP1[1,1]$</td>
<td>403</td>
</tr>
<tr>
<td>$TC_DP3[1,1]$</td>

<td>45</td>
</tr>
<tr>
<td>$TC_TPG9[5]$</td>
<td>3</td>
</tr>
</tbody>
</table>

Programming

```
N20 T1 D1 ;Select T1 and D1
N25 S1=1000 M1=3 ;1000 rev/min for spindle 1
N30 S2=1500 M2=3 ;1500 rev/min for spindle 2
...
N40 GWPSON ;GWPS selection for active tool T1
N45 S[$P\_AGT[1]$] = 60 ;Set GWPS for active tool to 60 m/s
    n=1909.85 min⁻¹
    ...
N50 GWPSON(5) ;GWPS selection for tool 5 (2nd spindle)
N55 S[$TC\_TPG1[5]$] = 40 ;Set GWPS for spindle 2 to 40 m/s
    n=1909.85 min⁻¹
    ...
N60 GWPSOF ;Switch off GWPS for active tool
N65 GWPSOF(5) ;Switch off GWPS for tool 5 (spindle 2)
...```

Note

Please refer to Section 2.4 for programming of tool monitoring function.

Supplementary references

References:  /FB/, P5, Oscillation
             /FB/, V1, Feeds, Multiple Feeds in a Block
             /FB/, SS, Synchronized Actions
2.5 Constant grinding wheel peripheral speed (GWPS)

Notes
Supplementary Conditions

Grinding-specific tool offset with grinding wheel peripheral speed

The function is available for
- SINUMERIK 840D/810D/FM-NC with SW 2 and higher

Continuous dressing (parallel dressing)

This function is an option and available for
- SINUMERIK 840D with NCU 572/573, with SW 2 and higher.

The function is contained in the export version 840DE with restricted functionality; it is not contained in the FM-NC, 810DE (SW 3.1 and earlier).
- The function is contained in the export version 810DE with restricted functionality in SW 3.2 and later.

Constant workpiece speed for centerless grinding

The function is contained in the export variant 810DE in SW 3.2 and later.

Remote diagnostic-Installing the TCP/IP protocol, 12102, 12103, 12104, 12105, 12106, 2/F3/1-32
REPOS, 2/M5/2-14
Response to setpoint changes, 2/S3/2-29
Restart, 2/B3/1-16
Reversal points, 2/P5/1-3
Rotary, Axis, 2/B3/1-23
Rotary axes, 2/R2/1-3
 Absolute dimension programming, 2/R2/2-11, 2/R2/2-14
Axis addresses, 2/R2/2-6
Feedrate, 2/R2/2-7
 Incremental dimension programming, 2/R2/2-13, 2/R2/2-15
 Mirroring, 2/R2/2-19
Modulo 360, 2/R2/2-9
Modulo conversion, 2/R2/2-11, 2/R2/2-14
Operating range, 2/R2/2-7
Position display, 2/R2/2-7
Software limit switches, 2/R2/2-19
Start-up, 2/R2/2-17
Units of measurement, 2/R2/2-7
Rotary axis, 2/R2/2-5, 2/T1/2-9
Rotary button pad, 2/B3/1-10
Rotary indexing machine, 2/B3/1-5, 2/B3/2-13
Rotation monitoring, 2/S6/1-3
Rotation monitoring error, 2/S6/3-21
Rotation monitoring ON/OFF, 2/S6/5-21
Runtime, 2/B3/1-12

S
Sag compensation, 2/K3/2-22
Compensation values in grid structure, 2/K3/2-31
SCALE, 2/R2/2-16
Second operator panel, 2/B3/1-19
Index

Secondary
Control panel, 2/B3/1-6, 2/B3/1-12
Unit, 2/B3/1-19
Selecting synchronous mode, 2/S3/2-9
Service case, 2/B3/1-18
Service display for FS, 2/S3/2-31
Service/installation and start-up, 2/B3/1-11
Servo enabling on SM-axis, 2/S3/2-29
Servo gain factor, 2/K3/2-47
Servo gain for SM control without measuring sys-
tem, 2/S6/3-17
Servo gain for SM control with measuring system,
2/S6/3-17
SERVO_FIFO_SIZE, 2/B3/4-98
Several NCUs, 2/B3/1-20, 2/B4/1-4
SW 3.5 and higher, 2/B3/1-22
Several operator panels
Alarm text storage, 2/B3/2-56
Alarms/messages, 2/B3/2-56, 2/B3/2-60
Applications, 2/B4/1-3
Availability, 2/B3/3-94, 2/B4/4-17
Buses, 2/B3/2-53
Configuration files, Number, 2/B3/2-52
Configurations, 2/B3/2-51
Connections, 2/B3/2-52
Defaults, 2/B3/2-37, 2/B3/2-54
Features in operation, 2/B4/2-15
Implementation in SW 3.1, 2/B3/1-19,
2/B4/1-3
Link check, 2/B3/2-56
NCU components, 2/B3/2-54
No. of communications partners, 2/B3/4-97
Operational characteristics, 2/B3/1-19
Operator interface, 2/B3/2-60
Operator panel components, 2/B3/2-53
Switchover of connection, 2/B3/2-55,
2/B3/2-56
Table of contents, 2/B3/i
User interfaces, 2/B4/1-4
Signal, Transformation active, 2/M1/5-75,
2/M5/5-27
Signals, 2/B3/1-7
Signals for 5th axis, 2/L1/5-19
Signals for digital and analog inputs/outputs,
2/L1/5-19
SIMATIC, 2/B3/2-35, 2/B3/2-54
SINCOM, 2/B3/1-6, 2/B3/2-30
Single block, 2/P2/2-8, 2/P2/2-17
SINUMERIK
810D, 2/B3/1-21
840D Installation Guide, 2/B3/1-12
Slide, 2/B3/1-23
Slimline screen, 2/B3/1-10
Softkey, 2/B3/1-10, 2/B3/1-16, 2/B3/1-20,
2/B3/1-21
Conn..., 2/B3/1-16
Software cams, 2/N3/2-5
Software limit switches, 2/H1/2-35, 2/R2/2-19,
2/T1/2-21
Sparking-out strokes, 2/P5/1-3
Speed, 2/H1/2-34
Speed control, 2/S6/1-3, 2/S6/2-8
Activation, 2/S6/2-14
Constant speed time, 2/S6/2-14
Knee-shaped acceleration characteristic,
2/S6/2-8
Response to acceleration rate changes,
2/S6/2-14
Speed monitoring, 2/W4/2-28
Speed ratio, 2/S3/2-7
Speed/acceleration limits, 2/S3/2-15
Spindle number, 2/W4/2-10
Spindle position with mono-probe, 2/M5/2-6
Spindle replacement, 2/K5/2-13
Spindle start-up, 2/S3/2-29
Spindle traversal in JOG mode, 2/H1/2-34
SRAM, 2/S7/2-5
SRAM memory requirements, 2/S7/2-25
Standard alarm texts, 2/B3/1-17
Start address of direct read input bytes of PLC
I/Os, 2/A4/4-47
Start address of direct write output bytes of PLC
I/Os, 2/A4/4-48
Start operating area, 2/B3/1-17, 2/B3/1-20
Start-up, 2/B3/1-17, 2/B3/1-18
Start-up and installation MMC 100.2, 2/F3/2-74
Start-up of neural QEC, 2/K3/2-69
Start-up tool, 2/B3/1-21
Static MMC property, 2/B3/1-12
Station/position change, 2/B3/1-26
Stepper motor control
Axis-specific machine data, 2/S6/4-19
Axis-specific signals, 2/S6/5-21
Interface signals, 2/S6/7-24
Machine data, 2/S6/7-23
Stepper motor drive without measuring system,
2/S6/3-18
Suitable probes, 2/M5/2-5
Suppression
Algorithm, 2/B3/1-13, 2/B3/2-39
Mechanism, 2/B3/1-10
Priority, 2/B3/1-12
Rules, 2/B3/2-40
Strategy, 2/B3/1-13, 2/B3/2-40, 2/B3/2-44
Switchover
Behavior OP030, MMC100, MMC102/103,
2/B3/1-16
Conditions, 2/B3/2-40
Symbol name, 2/B3/1-13, 2/B3/1-18
Synchronization cycle, 2/B3/1-8
Synchronized actions, 2/B3/1-27

SINUMERIK 840D/840Di/810D/FM-NC Extension Functions (FB2) – 04.00 Edition
Synchronous mode, 2/S3/2-5
Activate, 2/S3/2-19
Control dynamics, 2/S3/2-24
Deactivate, 2/S3/2-19
Feedforward control, 2/S3/2-24
Knee-shaped acceleration characteristic, 2/S3/2-25
Multiple couplings, 2/S3/2-24
Response to alarms, 2/S3/2-25
Speed/acceleration limits, 2/S3/2-24
Synchronous procedure, 2/S5/2-15
Synchronous spindle pair, 2/S3/2-5
System clock rate for FM NC with five axes-NC, 2/L1/3-15
System requirements, 2/M5/2-12
System variable, 2/M5/2-13, 2/M5/2-17
System variables, 2/B3/1-27
Global, 2/B3/1-27

T
T function, 2/W3/1-3
Temperature compensation
Coefficient \( \tan^\beta(T) \), 2/K3/2-11
Compensation equation, 2/K3/2-6
Deformation, 2/K3/2-5
Error curves, 2/K3/2-5
Monitoring functions, 2/K3/2-9
Parameters, 2/K3/2-8
Position display, 2/K3/2-9
Sensor technology, 2/K3/2-5
Temperature compensation, parameters, 2/K3/2-7
Temporary assignment, 2/B3/1-7
Terminal emulation, 2/F3/2-99, 2/F3/2-103
Test program for testing repeat accuracy, 2/M5/6-32
Threshold values, 2/S3/2-15
Threshold values for coarse/fine synchronism, 2/S3/2-31
Tolerance of BERO edges in pulses for monitoring stepper motor rotation, 2/S6/4-19
Tool change
Change point, 2/W3/1-3, 2/W3/2-7
Fixed points, 2/W3/2-7
Tool offset, 2/P2/2-16
Tool offset for grinding operations, 2/W4/2-5
Tool offset for grinding tools, 2/W4/2-5
Tool types for grinding tools, 2/W4/2-9
TRAANG, 2/M1/1-6, 2/M1/2-39
Activation, 2/M1/2-48
Availability, 2/M1/3-59
Deactivation, 2/M1/2-48
Number of, 2/M1/2-42
Preconditions, 2/M1/2-41
Restrictions, 2/M1/2-49
Specific settings, 2/M1/2-44

TRACYL, 2/M1/1-6, 2/M1/2-28
Activation, 2/M1/2-36
Availability, 2/M1/3-59
Axis image, 2/M1/2-33
Deactivation, 2/M1/2-37
Number of, 2/M1/2-30
Preconditions, 2/M1/2-30
Restrictions, 2/M1/2-37
Specific settings, 2/M1/2-33
TRANS, 2/R2/2-16
Transformation, Chaining sequence, 2/M1/2-52
TRANSMIT, 2/M1/1-5, 2/M1/2-9
Activation, 2/M1/2-16
Availability, 2/M1/3-59
Axis image, 2/M1/2-13
Deactivation, 2/M1/2-16
Restrictions, 2/M1/2-17
Specific settings, 2/M1/2-13
TRANSMIT structures, Number of, 2/M1/2-10
Transverse axes, 2/H1/2-37
Transverse grooves, 2/M1/1-6
Traverse against fixed stop, 2/S6/3-17

U
User, Alarm, 2/B3/1-17
User communication, 2/B3/1-7
Utilization property, 2/B3/1-12

V
VDI signals when stepper motor is used, 2/S6/3-18
Velocity, 2/H1/2-6, 2/H1/2-16
Velocity and acceleration, 2/H1/2-36
Velocity coupling, 2/S3/2-31
Viewer MS-DOS (MMC 100.2), 2/F3/2-84
Viewer PC functions, 2/F3/2-100

W
WAITP, 2/P2/2-7, 2/P2/2-15
Oscillation axis, 2/P5/2-17
Working area limitation, 2/H1/2-35
Working area limitations, 2/R2/2-19
Workpiece clamping, 2/B3/1-23, 2/B3/1-27
Write continuously, 2/W4/2-20
Write online tool offset discretely, 2/W4/2-24
Write real-time variable, 2/S5/2-24
