# SIMODRIVE 611 digital

## Drive Converters

### Configuration Manual

- Preface, Table of Contents
- Overview of the Drive System
- System Configuration
- Motor Selection and Position/Speed Sensing
- Control Units
- Power Modules
- Infeed Modules
- Line Supply Connection
- Important Circuit Information
- Cabinet Design and EMC
- Connection Diagrams
- Service and Spare Parts
- Dimension Drawings
- Abbreviations and Terminology
- References
- Certificates/Declarations of Conformity
- Index

**Valid for**

*Equipment series 6SN11*–*
**SIMODRIVE® documentation**

**Printing history**
Brief details of this edition and previous editions are listed below. The current configuring manual replaces the previous version.

The status of each edition is shown by the code in the "Remarks" column.

**Status code in the "Remarks" column:**

- A.... New documentation
- B.... Unrevised reprint with new Order No.
- C.... Revised edition with new status

Foreword

Reader’s note
The Configuration Manual describes a reference state, which when observed, ensures the required reliable operation and compliance with the standards that have been taken into account.

For deviations from the requirements laid down in the Configuration Manual, suitable measures must be applied, for example, measurements, securing or verifying that the required reliable operation is guaranteed and that the standards to be taken into account are complied with from a regulatory perspective.

The documentation must be completely read, understood and taken into account before the devices are commissioned.

If parts of the documentation have not been adequately understood, then please contact your local Siemens person before you continue to work with the devices.

The contents of this document are neither part of an earlier or existing agreement, commitment or contractual relationship, nor do they change this. Siemens is obliged to fulfill all requirements specified in the applicable sales contract, which also contains all the valid terms of warranty.

Any statements contained herein neither create new warranties nor modify the existing warranty.

Structure of the documentation
The SIMODRIVE documentation is subdivided into the following levels:
- General Documentation/Catalogs
- User Documentation
- Manufacturer/Service Documentation

Additional information
You can find information on the following topics under the following link:
- Ordering documentation/overview of documents
- Links to download documents
- Using documentation online (searching and scanning through manuals/information)

http://www.siemens.com/motioncontrol/docu

If you have any questions regarding the technical documentation (e.g., suggestions, corrections), then please send an e-mail to the following address
docu.motioncontrol@siemens.com

Software download
You can find the software under the following internet address:
https://support.automation.siemens.com

—> Produkt Support —> Drive Technology —> Converters —> Low-voltage Converters —> SIMODRIVE Converter system —> SIMODRIVE POSMO
Entry type: Download
Search item: SimoCom U
Information is provided under the following link as to how you can individually compile documentation based on Siemens content, and adapt this for your own machine documentation:
http://www.siemens.com/mdm

Information about SITRAIN – Siemens training courses for products, systems and solutions in automation technology – is provided under the following link:
http://www.siemens.com/sitrain

You can find Frequently Asked Questions in the Service&Support pages under Product Support:
http://support.automation.siemens.com

This documentation addresses machine manufacturing companies (OEMs) that wish to configure, construct and commission a drive line-up based on SIMODRIVE components.

Local country telephone numbers for technical support are provided in the Internet under Contact:
http://support.automation.siemens.com

You will find the certificates for the products described in this documentation in the Internet: http://www.support.automation.siemens.com under the Product/Order No. 15257461 or contact the relevant branch office of the A&D MC group of Siemens AG.

All declarations of conformity and certificates such as CE, UL, etc., are performed with the system components described in the associated Configuration Manuals or catalogs and, thus, are only valid if the described components are used in the device or facility.

The use of components not released by Siemens may require the user to prepare new certificates/declarations of conformity.
Note
Repairs may be performed only by workshops authorized by Siemens who must use genuine spare parts. Unauthorized repairs and the use of other spare parts can result in personal injuries and property damage as well as loss of UL approvals and safety functions, such as Safety Integrated.

Warning
SIMODRIVE converters are used in high voltage installations and are operated at voltages that when touched can cause serious injuries or death!

Proper use
Note the following:

Warning
Siemens products may only be used for the intended use in applications described in the catalog and the associated technical documentation. If third-party products and components are used, then these must either be recommended or certified by Siemens. The perfect and safe operation of products assumes that they have been correctly transported, correctly stored, located, mounted, installed, commissioned, operated and maintained. The permissible environmental conditions must be complied with.

Information and instructions in the associated documentation must be observed.

Definition: Who are qualified personnel?
Setup and operation of the device/equipment/system in question must only be performed using this documentation. Commissioning and operation of a device/system may only be performed by qualified personnel. Qualified personnel as referred to in the safety instructions in this documentation are persons authorized to start up, ground, and label devices, systems, and circuits in accordance with the relevant safety standards.

Objectives
This Configuration Manual provides all of the detailed information required to use and handle SIMODRIVE components.

Should you wish for additional information or should exceptional problems arise that are not addressed in sufficient detail in this manual, you can request the required information from your local Siemens office.

The Configuration Manual describes a modular drive system. It is permissible to use the constellations and general versions described here. All other combinations must be separately and individually released by Siemens.
Information for using this Manual

The following should be observed when using this manual:

1. Help: The following help is available for the reader:
   - Complete table of contents
   - Header line (as orientation):
     the main chapter is in the upper header line
     the sub–chapter is in the lower header line
   - Appendix with
     – Abbreviations and List of References
     – Index
     If you require information regarding a specific term, then look for this in
     the Appendix under the Chapter "Index".
     The Chapter number as well as the page number is specified where in-
     formation on this term can be found.

2. Edition of the documentation:
   The history of the document editions is summarized in the printing history.

Reader’s note

Only the digital components for a SIMODRIVE group with High Performance/
High Standard and 611 universal modules are described in Edition A10.04 and
higher. Please refer to the overview in Chapter 4.1 regarding from which
software releases, use is possible.

The descriptions for the relevant controls in the Configuration Manual, Edition
02.03, still remain valid for the analog components that have been discontinued
(not for new configurations)!

Safety information

This documentation contains information that must be observed to ensure your
personal safety and to prevent material damage. The instructions for your per-
sonal safety are marked by a warning triangle. Instructions relating solely to
material damage are not marked by a warning triangle. The warnings appear in
decreasing order of risk as given below.

Danger

indicates that death or serious injury will result if proper precautions are not
taken.

Warning

indicates that death or serious injury may result if proper precautions are not
taken.
Caution
with a safety alert signal indicates that minor personal injury can result if proper precautions are not taken.

Caution
without a safety alert symbol, indicates that property damage can result if proper precautions are not taken.

Notice
indicates that an undesirable result or state may arise if the relevant note is not observed.

Warning: High leakage current
As a result of the high switching frequencies, capacitances (parasitic and integrated) with respect to ground may cause high leakage currents. This is the reason that a permanent PE connection is required at the control cabinet and at the line filter!
Measures according to EN 50178/94 Part 5.3.2.1 must be implemented, e.g.
1. Copper protective conductor with a minimum cross-section of 10 mm² should be connected, or
2. A second conductor should be connected in parallel with the protective conductor through separate terminals.
This conductor must also fully meet the requirements for PE conductors according to IEC 364–5–543.
Note
The SIMODRIVE 611 drive converter system can be directly connected to TN line supplies with rated voltages 3–ph. 380 V AC (with derating), 3–ph. 400 V AC, 3–ph. 415 V AC and 3–ph. 480 V AC. Matching transformers, which are tailored to the system, are available to connect the system to other line supply types, for example, to IT or TT line supplies.

Upstream devices providing protection against hazardous leakage currents or for fire protection (such as residual–current protective devices) must be AC/DC–sensitive in accordance with the requirements of DIN EN 50178. In the case of other residual current protective devices, a transformer with separate windings must be connected upstream of the converter for purposes of decoupling. See Chapter 7.

Warning
When electrical equipment is operated, certain parts of this equipment are inevitably under dangerous voltage.

Incorrect handling of these units, i.e. not observing the warning information, can therefore lead to death, severe bodily injury or significant material damage.

Only appropriately qualified personnel may commission/start up this equipment.

These personnel must be thoroughly familiar with all warnings and maintenance procedures described in these operating instructions.

Perfect, safe and reliable operation of the equipment assumes that it has been appropriately transported and repaired and professionally stored, mounted and installed as well as carefully operated and serviced. Failure to observe these requirements can endanger the user (electrical shock, fire hazard) or damage the device.

Hazardous axis motion can occur when working with the equipment.

Further, all of the relevant national, local land plant/system–specific regulations and specifications must be taken into account.

Caution
The DC link discharge voltage hazard warning in the local language must be clearly attached to the appropriate modules.

Note
When handling cables, please observe the following:

- are not damaged
- they may not be stressed,
- they may not come into contact with rotating components.
Notice
M600 and M500 are not PE voltages. Hazardous voltages of between 300 ... 400 V with respect to PE are present at the terminals. These potentials (voltages) may not be connected to PE.

Note
The machine builder must ensure that the voltage drop between the start of the consumer’s installation and the power drive system (PDS) does not exceed 4% when operating with rated values.

Warning
The “protective separation” can only be guaranteed when using the components permitted/certified by Siemens for the system.

“Protective separation” can only be guaranteed when it is absolutely certain that the system components have the appropriate degree of protection.

The ensure “protective separation”, the shield of the brake cable must be connected to PE through the largest possible surface area.

“Protective separation” is required between the temperature sensor and motor winding.

If these limitations and constraints are not carefully observed then this can result in injury due to electric shock.

Warning
Start–up/commissioning is absolutely prohibited until it has been ensured that the machine in which the components described here are to be installed, fulfills the regulations/specifications of the Directive 89/392/EEC. If this is not observed, this can result in injury.

Warning
The information and instructions in all of the documentation supplied and any other instructions must always be observed to eliminate hazardous situations and damage.

• For special versions of the machines and equipment, the information in the associated catalogs and quotations applies.

• Further, all of the relevant national, local land plant/system–specific regulations and specifications must be taken into account.

• All work should be undertaken with the system in a no–voltage condition!

If this is not observed, this can result in injury.
Warning
Even after the disconnection of all power, a dangerous residual voltage greater than 60 V\textsubscript{DC} can still be present. With capacitor modules, this hazardous voltage can be present for up to 30 min.

In order to ensure that no hazardous voltages are present, the voltage must be first carefully measured (generator principle when motors are rotating). If this is not observed, then this can result in injury due to electric shock.

For this reason, opening the device or removing the cover is permitted only after up to 30 minutes have elapsed (depending on the degree of expansion) since the device was switched to the voltage–free state. All covers must be reattached before the line voltage is switched on. Operation of the plant with damaged DC link covers is not permitted!

Danger of death!
Touching live terminals, cables or device parts can result in serious injury or death!

---

Warning
Do not switch off devices, e.g. using a line supply isolating device (main switch), before disabling the pulse inhibit (T 48) on the infeed/regenerative feedback modules. Otherwise, the device can be destroyed along with other devices in the control cabinet.

---

Warning
The rated current of the connected motor must match the rated converter current. If this is not the case, then the protection of the motor cables is no longer guaranteed. The cross–section of the motor feeder cable must be dimensioned for the rated drive converter current. If this is not carefully observed, cables can overheat and can even cause an equipment fire.

---

Caution
When using mobile radios (e.g. cellular phones, mobile phones, 2–way radios) with a transmission power of > 1 W close to the equipment (< 1.5 m) the function of the equipment can be disturbed.

---

Note
This device/module is an open–type device corresponding to UK 50 and, thus, may only be operated in enclosures/cabinets that ensure protection against mechanical damage. To ensure protection against mechanical damage, the devices may only be operated in enclosures/cabinets with degree of protection IP54 in accordance with EN 60529.
Note
The terminal blocks of the SIMODRIVE 611 modules are used for electrical connection of the particular module. If the terminal blocks are used for another purpose (e.g. to carry the module), this can damage the module. If the insulation is damaged, then this can cause injury due to electric shock.

Note
For a minimum fault current, the machine manufacturer must ensure that the upstream overcurrent protection devices trip within 5 s (see Chapter 7.3; Table 7–5 and Fig. 7–8)

Note
The following secondary conditions/limitations must be carefully observed if the machine is subject to a high–voltage test:

1. Power–down the unit.
2. Withdraw the overvoltage module in order to prevent the voltage limiting responding.
3. Disconnect the line filter.
4. Connect M600 to PE through resistor 100 kΩ (the grounding clip in the NE modules is open). In the factory, the units are subject to a high–voltage test at 2.25 kVDC phase–PE. The NE modules are shipped with the grounding clip open.
5. The maximum permissible voltage for a high–voltage machine test is 1.0 kVDC phase–PE.

Danger
The control and drive components for a power drive system (PDS) are allowed for industrial and commercial use in industrial networks. Their use in public networks requires a different configuration and/or additional measures.
ElectroStatic Discharge Sensitive Devices

Components, which can be destroyed by electrostatic discharge are individual components, integrated circuits, or boards, which when handled, tested, or transported, could be destroyed by electrostatic fields or electrostatic discharge. These components are referred to as ESDS (ElectroStatic Discharge Sensitive Devices).

Handling ESDS modules:

- When handling devices which can be damaged by electrostatic discharge, personnel, workstations and packaging must be well grounded!
- Generally, electronic modules may not be touched unless work has to be carried out on them.
- Personnel may only touch components if
  - they are continuously grounded through ESDS wristlets,
  - they wear ESDS shoes, ESDS shoe grounding strips in conjunction with an ESDS floor surface.
- Boards/modules must only be placed on conductive surfaces (table with ESDS surface, conductive ESDS foam, ESDS packaging, ESDS transport container).
- Modules may not be brought close to data terminals, monitors or television sets (minimum clearance to the screen > 10 cm).
- Do not bring ESDS–sensitive modules into contact with chargeable and highly–insulating materials, such as plastic sheets, insulating table tops or clothing made of synthetic materials.
- Measuring work may only be carried out on the components if
  - the measuring unit is grounded (e.g. via a protective conductor) or
  - when floating measuring equipment is used, the probe is briefly discharged before making measurements (e.g. a bare–metal control housing is touched).

Warning

If static discharge occurs on surfaces or interfaces that cannot be easily accessed, malfunctions and/or defects will result.

Warning

When the system boots, this represents a critical operating state with increased risk. In this phase, especially when activating drives, it is not permissible that personnel are close to the hazardous area.

Warning

After hardware and/or software components have been modified or replaced, it is only permissible that the system runs–up and the drives are activated with the protective devices closed (could possibly result in death). Personnel shall not be present within the danger zone. It may be necessary to carry–out a new, partial or complete acceptance test after every change or replacement.

Before entering the hazardous area, it should be carefully checked that all of the drives exhibit stable behavior by briefly moving the drives in both directions (+/–).
Warning

If the “safe standstill” function or a stop function, Category 0 in accordance with EN 60204–1, is activated, the motor can no longer provide any torque. As a result of this, potentially hazardous motion can occur, e.g. for:

- When the drive axes are subject to an external force.
- Vertical and inclined axes without weight equalization.
- Axes that are moving (coasting down).
- Direct drives with low friction and self–clocking behavior.

Possible hazards must be clearly identified using a risk analysis that must be carried out by the manufacturer. Using the assessment based on this risk analysis, it must be defined as to which additional measures are required (e.g. external brakes).

Warning

If the “safe standstill” function is activated, when a fault condition occurs, the mechanical axis system can make a jerky movement (possibility of injury, crushing) as a result of the principle of operation. The magnitude of this movement depends on the following parameters:

- Design/configuration and mechanical ratios between the motor/mechanical system.
- Speed and acceleration capability of the motor
- Magnitude of the selected monitoring clock cycle.
- Size of the selected standstill tolerance window.

The danger and warning information above must always be unconditionally observed in order to avoid personal injury and property damage.
The professional associations for precision and electrical engineering specify limits for electrical load in the workplace. Compliance with Federal Emission Control Law is mandatory in the Federal Republic of Germany!

Adherence to the RFI suppression limits for EMC does not also ensure adherence to the requirements for workplaces.

In particular, machine construction, control cabinet structure, shop environment, infeed conditions and other installations have a substantial impact on adherence to the limits required by the trade association for the respective workplace.

Therefore, the operator must always clarify whether wearers of pacemakers may be employed at the planned workplace without endangering their health.
Residual risks

When carrying out a risk assessment of the machine in accordance with the EU Machinery Directive, the machine manufacturer must consider the following residual risks associated with the control and drive components of a power drive system (PDS).

1. Unintentional movements of driven machine components during commissioning, operation, maintenance, and repairs caused by, for example:
   - Hardware defects and/or software errors in the sensors, controllers, actuators, and connection technology
   - Response times of the controller and drive
   - Operation outside the specification
   - Errors when parameterizing, programming and wiring
   - Use of radio devices/cellular phones in the immediate vicinity of the controller
   - External effects

2. Exceptional temperatures as well as emissions of light, noise, particles, or gas caused by, for example:
   - Component malfunctions
   - Software errors
   - Operation outside the specification
   - External effects

3. Hazardous shock voltages caused by, for example:
   - Component malfunctions
   - Static charges
   - Operation outside the specification
   - Condensation/conductive contamination
   - External effects

4. Electrical, magnetic, and electromagnetic fields that can pose a risk to people with a pacemaker and/or implants if they are too close.

5. Emission of pollutants if components or packaging are not disposed of properly.

An assessment of the residual risks (see points 1 to 5 above) established that these risks do not exceed the specified limit values (risk priority number in accordance with EN 60812 RPZ = 100).

For additional information, refer to the relevant sections of the Configuration Manual.

Warning

In case of failure exceptional high temperatures including open fire within and outside the inverter as well as emissions of light, noise, particles, or gas can appear caused by e.g.

- Component malfunctions
- Software errors
- Operating and/or ambient conditions not within the scope of the specification
- External influences / damage

These open type/IP20 inverters must be installed inside a metal enclosure (or be protected by another equivalent measure) sufficient to prevent all contact with fire, within and outside the inverter.
At the present time, other known residual risks are:

- Acceleration of the spindle or axes due to:
  - Encoder errors, e.g. errors in the absolute measuring system (CD track),
    loose contacts in encoder cables or unsuitable encoders.
  - Cyclically interchanged phases of the motor connections
  - Interchanged control sense.
  - Electric faults (defective components, etc.).
  - Operation of a demagnetized synchronous motor with saturation–based
    pole position identification.
  - Transfer of an incorrect, but plausible actual value in absolute measuring
    systems (encoder does not signal an error).

- If two power transitions in the inverter are simultaneously destroyed, de-
  pending on the motor pole number, this can cause brief axis movement.
  - Example: Synchronous motor:
    For a 6–pole synchronous motor, the maximum mechanical motion
    on the motor shaft can be 30 degrees.
    With a ballscrew that is directly driven (e.g. 10 mm per revolution) this
    corresponds to a maximum linear motion of approximately 0.8 mm.
  - Example, synchronous linear motor:
    For a synchronous linear motor, the movement can be a maximum of
    one pole width, refer to the Motors Configuration Manual.

- For a 1–encoder system, encoder faults are detected by various HW and
  SW monitoring functions. It is not permissible that these monitoring functions
  are deactivated and they must be parameterized carefully.

- Stop function Category 0 according to EN 60204–1 means that the spindle/
  axes are not braked. Depending on the kinetic energy involved, they can
  coast–down for a long time.
  This must be integrated in the logic of the protective door interlocking (e.g.
  with a logic operation with the signal n < nx).

- Violation of limits may briefly lead to a speed higher than the speed setpoint,
  or the axis may pass the defined position to a certain extent, depending on
  the dynamic response of the drive and on parameter settings (MD).

- Parameterization and programming errors made by the machinery construc-
  tion OEM cannot be identified. The required level of safety can only be
  assured by a thorough and careful acceptance testing.

- When replacing power modules or motors, the same type must always be
  used as otherwise the selected parameters may result in different re-
  sponses.
  When an encoder is replaced, the axis involved must be re–calibrated.

- If the line infeed units are connected to the line supply, where the minimum
  short–circuit current is not reached, then the overcurrent protection devices
  will not be able to trip within the appropriate time. There is a risk of fire in the
  case of a fault!

1 Overview of the Drive System

1.1 Overview of SIMODRIVE 611

Note
Siemens accepts the warranty for satisfactory and reliable operation of the drive system under the clear understanding that only original SIMODRIVE system components are used in conjunction with the original accessories described in this Configuration Manual and in Catalog NC 60.

The user must take the planning and engineering data into consideration.

Combinations that differ from the engineering specifications – where relevant, also in conjunction with third-party products, require a special, contractual agreement.

The converter system is designed for installation in control cabinets which conform with the relevant standards for processing machines, especially EN 60204.

Description
The converter system comprises the following modules (refer to Fig. 1-2 and 1-3):

- Transformer
- Switching and protective elements
- Line filter
- Commutating reactors
- Infeed modules
- Power modules
- Control units harmonized to the application technology/process and motor types
- Special modules and other accessories

Various cooling methods are available for the power-dependent line supply infeed and drive modules:

- Internal cooling
- External cooling
- Hose cooling
1.2 Engineering steps

Note
Depending on the result of a hazard analysis/risk assessment to be performed according to the Machinery Directive 98/37/EC and EN 292–1, EN 954–1, EN ISO 13849–1 and EN 1050, the machinery construction company must configure, for all its machine types and versions, the safety–relevant control sections for the complete machine, incorporating all of the integrated components. These also include the electric drives.

Note
When engineering SIMODRIVE 611, it is assumed that the motors to be used are known.

Reference: refer to the appropriate references for motors in the Appendix

Procedure
A SIMODRIVE drive group is configured in two phases:

- Phase 1 Selecting the components (refer to Fig. 1-4)
- Phase 2 Connection configuration (refer to Fig. 1-5)

Note
A selection guide is available for engineering the 6SN series, e.g.:

- NCSD Configurator

For additional information, please contact your local Siemens office.

The functions of SIMODRIVE control units are described with keywords in this Configuration Manual. Limit values may be specified in some cases. For additional details, please refer to the appropriate documentation.

Detailed ordering information and instructions are provided in Catalogs NC 60 and NC Z.
1 Overview of the Drive System

1.2 Engineering steps

Phase 1 when engineering

Selecting components

- Motor selection — See Chapter 3
- Position sensing — See Chapter 3
- Control units — See Chapter 4
- Power modules — See Chapter 5
- Infeed modules — See Chapter 6
- Line supply connection — See Chapter 7

Fig. 1-4 Selecting components

Phase 2 when engineering

Connecting–up

- Important circuit information — See Chapter 8
- Cabinet design and EMC — See Chapter 9
- Block diagrams — See Chapter 4
- Connection diagrams — See Chapter 10
- Dimension drawings — See Chapter 12

Fig. 1-5 Connecting–up

Selecting cables, cable protection and switching devices

Cables, cable protection and switching devices must be selected carefully taking into account the relevant regulations, standards and the requirements of the location where the system is installed.

Reference: /NCZ/ Catalog, Connecting System and System Components
Reference: /NSK/ Catalog, Low Voltage Switchgear
1.3 Engineering a drive

Dimensioning

The power modules are selected depending on the motors to be used and the drive requirements (torque, speed ratio).

The infeed module is selected using the DC link power required by the group and the active power requirement of all of the power modules:

- Taking into account the coincidence factor (value determined from the load duty cycle or experience value). Not all of the motors are subject to a full load at the same time.
  —> refer to Fig. 1-6
- The maximum permissible power to charge the DC link capacitors.
  —> refer to Chapter 6.6 and Table 1-4

When calculating the DC link power $P_{2K}$, refer to Fig. 1-6.

Feed axes

In this case it must be noted that the DC link will be over-dimensioned if the motor outputs are simply added together:

- Because, from experience, feed axes are not operated at their rated torque and rated speed
- Because generally, the feed drives are not simultaneously operated

In the engineering sheet (refer to Fig. 1-6) to calculate the DC link power, these factors are taken into account by the speed ratio $n/n_N$ (ratio between the operating speed and the rated speed) and coincidence factor $K$.

Power supply rating

Gating and electronic points used to determine the load limits of the power supply. It is not possible to specify the power rating of an individual voltage source as several power supplies are coupled with one another. If the number of gating or electronic points is exceeded, an additional power supply must be used – the "monitoring module".

When determining the gating (AP) and electronic points (EP) refer to Chapter 6.6.

When calculating the power supply rating, refer to Chapter 1.3.5.

DC link capacitance

Every infeed module has a maximum value that applies when expanding the DC link capacitors. It must be ensured that the DC link capacitance in the selected drive group is not exceeded (refer to Table 1-1).

The sum (total) of the DC link capacitances (refer to Chapter 1.3.5, Table 1-4) of all modules must be less than or equal to the charge limit corresponding to the following table of the infeed modules:
### 1.3 Engineering a drive

### 1.3.1 Calculation of the required DC link power ($P_{ZK}$) for dimensioning the supply system, infeed unit

**Steady-state operation:**

\[ P_{ZK} = P_{VSA \, ZK} + P_{MSD \, ZK} \]

\[ P_{ZK} \leq P_{n \text{ infed \, module}} \]

- **Feed axes with rotary motors**
  
  The following formula is used in the engineering sheet to determine the calculated power:

\[ P_{\text{calc \, FD}} = 0.105 \cdot M_0 \cdot n_n \cdot 10^{-3} \, [kW] \]

Where:

- $P_{\text{calc \, FD}}$: calculated power for feed axes [kW]
- 0.105: factor $2 \cdot \pi / 60$
- $M_0$: stall torque [Nm]
- $n_n$: rated speed [RPM]

- **Feed axes with linear motors**

\[ P = F_n \cdot V_{\text{MAX, } F_n} \cdot 10^{-3} \, [kW] \]

Where:

- $F_n$: rated force [N]
- $V_{\text{MAX, } F_n}$: maximum velocity at the rated force [m/min]

The DC link power $P_{VSA \, ZK}$ of the feed axes is calculated using the engineering sheet. The following factors must be taken into account:

- Speed ratio $\bar{n}/n_N$
- Coincidence factor $K$ for the number of feed axes per area

If the exact values of the speed ratio $\bar{n}/n_N$ and coincidence factor $K$ are known for the application in question, these should be used.

- **Main spindles**

  For main spindle drives, the efficiencies must be included in the calculation and are roughly estimated using the following factors:

  - **Motors**
    
    \[ P_{MSD \, ZK} \leq 4 \, kW \]
    
    \[ P_{MSD \, ZK} = 1.45 \cdot P_{\text{MSD motor shaft}} \, [kW] \]
    
    \[ P_{MSD \, ZK} > 4 \, kW \]
    
    \[ P_{MSD \, ZK} = 1.25 \cdot P_{\text{MSD motor shaft}} \, [kW] \]

Where:

- $P_{MSD \, ZK}$: DC link power for the main spindle drive [kW]
- 1.45 or 1.25: Assumed factor for the motor efficiency
- $P_{\text{motor shaft \, MSD}}$: mechanical power [kW] used at the shaft of the main spindle motor

The rated motor current may not exceed the rated output current of the power modules. The maximum motor current must always be less than the maximum converter current.
1.3.2 Dynamic operation

The peak infeed power must also be calculated for acceleration and deceleration operations.

- **Feed axes**
  
  The peak infeed power expected for feed axes can be roughly calculated according to the following formula:

  \[
  P_{S\,FD} = 0.6 \cdot V_{DC\,link} \cdot I_{max} \cdot \frac{n}{n_N} \cdot 10^{-3} \ [kW]
  \]

  Where:
  
  - \( P_{S\,FD} \): peak infeed power (calculated) [kW] for feed axes
  - 0.6: empirical factor: DC link energy and EMF of the motor are taken into account
  - \( V_{DC\,link} \): DC link voltage [V] (600 V)
  - \( I_{max} \): peak current [A] set for an axis
  - \( \frac{n}{n_N} \): max. axis speed referred to the motor rated speed

- **Feed axes with linear motors**
  
  \[
  P_{S\,FD} = F_{MAX} \cdot V_{MAX, FMAX} + \left(\frac{I_{MAX}}{I_N}\right)^2 \cdot P_{VN} \ [kW]
  \]

  \[
  = 0.5 \ldots 0.9 \cdot 0.9 \cdot U_{ZK} \cdot I_{MAX} \cdot \frac{v}{V_{MAX, FMAX}} \cdot 10^{-3} \ [kW]
  \]

  Where:
  
  - \( F_{MAX} \): maximum force [N]
  - \( V_{MAX, FMAX} \): maximum velocity at the maximum force [m/min]
  - \( I_{max} \): peak current [A] set for an axis
  - \( I_N \): rated current [A] set for an axis
  - \( P_{VN} \): rated motor power loss [kW]
  - \( \frac{v}{V_{MAX, FMAX}} \): max. axis velocity referred to the maximum velocity at the maximum force

- **Main spindles**
  
  The peak infeed power expected for main spindles is calculated according to the following formula:

  - **Motors**
    
    \[
    P_{S\,MSD} = 1.45 \cdot P_{S\,motor\,shaft\,MSD} \ [kW]
    \]
    
    \[
    \leq 4 \ kW
    \]

  - **Motors**
    
    \[
    P_{S\,MSD} = 1.25 \cdot P_{S\,motor\,shaft\,MSD} \ [kW]
    \]
    
    \[
    > 4 \ kW
    \]

  Where:
  
  - \( P_{S\,MSD} \): peak power (calculated) for main spindles [kW]
  - 1.25 or 1.45: factor to take into account the motor efficiency
  - \( P_{S\,motor\,shaft\,MSD} \): peak power [kW] used at the shaft of the main spindle motor

The sum of \( P_{S\,FD} \) and \( P_{S\,MSD} \) should be calculated from all of the feed axes and main spindles that are simultaneously operated. This calculated power must be less than the peak power of the regenerative feedback module.
1.3.3 Braking operation

With the UI modules, only deceleration with pulsed resistors is possible. With I/R modules, a regenerative feedback of excess energy to the supply system also occurs. For required braking operations in the event of a power failure, the braking module and pulsed resistors are also needed.

The regenerative feedback power is dependent on the available energy to be braked in the system:

- The mass
- Speed/velocity
- Braking ramps/braking time
- Efficiencies

1.3.5 Checking the permissible power supply rating

The infeed or monitoring module used offers a basic equipping of the electronic (EP values) and control power supply (AP values).

The following table is used to determine the power supply requirement of a drive line-up.

The number of modules used should be entered. The product from "Evaluation factor individual module" and "Number of modules" should be formed.

An (additional) monitoring module must be provided if one of these values is exceeded. The following tables should be used again for the module line-up, supplied from the monitoring module.

The monitoring module must be located to the left in front of the modules to be monitored.

System Configuration

Drive line–up

A SIMODRIVE drive group has a modular configuration comprising line filter, commutating reactor, line supply infeed module, drive modules as well as, when required: monitoring, pulsed resistor and capacitor module(s).

Satisfactory operation is ensured only in conjunction with the components that are described in this Configuration Manual or published in the Catalog NC60 (Internet Mall) and with adherence to the required boundary/application conditions.

Failure to observe this along with improper use and application conditions can void your certifications, conformity declarations or warranty claims. In order to avoid contamination, the modules should be installed in a control cabinet with degree of protection IP 54.

Modules can also be arranged in several tiers one above the other or next to one another.

Note

Tightening torques for screw connections are:

<table>
<thead>
<tr>
<th>Screw size</th>
<th>→ tightening torque</th>
</tr>
</thead>
<tbody>
<tr>
<td>M3</td>
<td>→ 0.8 Nm</td>
</tr>
<tr>
<td>M4</td>
<td>→ 1.8 Nm</td>
</tr>
<tr>
<td>M5</td>
<td>→ 3.0 Nm</td>
</tr>
<tr>
<td>M6</td>
<td>→ 6.0 Nm</td>
</tr>
<tr>
<td>M8</td>
<td>→ 13.0 Nm</td>
</tr>
<tr>
<td>M10</td>
<td>→ 25.0 Nm</td>
</tr>
<tr>
<td>Tolerance</td>
<td>→ 0/+30%</td>
</tr>
</tbody>
</table>

For tightening torque deviations for connections to the HF/HFD reactors, see the specifications in Chapter 6.5.

The screws at terminal connections, e.g. DC link busbars, terminals should be checked and tightened each time that the equipment is transported or when performing maintenance work, however at the latest after 5 years.

Note

According to IEC 61800–5–1, a PDS (Power Drive System) with leakage currents over 3.6 mA requires a secure ground connection (e.g. at least 10 mm² Cu or multiple connection) or an automatic shutdown in case of a ground connection fault.

The housings of the SIMODRIVE 611 converter system modules are enclosed and EMC–compatible as specified in EN 60529 (IEC 60529).

The electrical system is designed to comply with EN 50178 (VDE 0160) and EN 60204, and an EC declaration of conformity is available.

The connections in the module group, motor cables, encoder lines and bus lines must be made using preassembled MOTION–CONNECT lines (see Catalog NC 60).
2.1 **Arrangement of the modules and their mounting**

2.1.1 **Arrangement of the modules**

The modules must be arranged in a particular layout. The following criteria must be taken into account:

- Function of the module
- Cross-section of the DC link busbar

The I/R or UI module is always located to the left of the module group at the beginning. The power modules (PM) are located to the right next to the I/R or UI modules (refer to Fig. 2-1).

Due to the limited conductivity of the DC link busbars of the modules with module width \( \leq 150 \text{ mm} \), the DC link power \( P_{ZK} \) of these modules must not exceed 55 kW. **Larger DC link busbars** must be used if this restriction cannot be complied with (refer to Fig. 2-2 and 2-3).

The DC link power \( P_{ZK} \) of the subsequent modules is calculated according to the engineering rule specified in Chapter 1.3.

The larger DC link busbars can be ordered as a set with Order No. [MLFB] 6SN1161–1AA02–6AA0. The set includes reinforced DC link busbars for module widths 50 mm, 100 mm and 150 mm.

The standard DC link brackets between the modules may not be changed, even when strengthened DC link busbars are used.
2 System Configuration

2.1 Arrangement of the modules and their mounting

Fig. 2-2  Module group without larger DC link busbars

Fig. 2-3  Module group with larger busbars

Note:
Reinforced DC link busbars must be used in the modules
## 2.1 Arrangement of the modules and their mounting

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
</tr>

<tbody>
<tr>
<td><strong>Pulsed resistor module</strong></td>
<td>Subject to certain conditions, several pulsed resistor modules can be connected in parallel (refer to Chapter 1.3.5, Table 1-4).</td>
</tr>
<tr>
<td><strong>Drive bus</strong></td>
<td>The drive bus length may not exceed 11 m. For more than six modules, control units, round cables must be used (refer to Chapter 2.1.2).</td>
</tr>
<tr>
<td><strong>Equipment bus</strong></td>
<td>The equipment bus cable that is looped-through a drive group at an infeed or monitoring module may not exceed 2.1 m from the supply connection point. For a two-tier configuration, two equipment bus branches are possible, each with a maximum length of 2.1 m from the branch point at the supply connection point.</td>
</tr>
<tr>
<td><strong>Cable length</strong></td>
<td>The permitted cable lengths depend on the used line filters, refer to the line filters in Section 7.4.</td>
</tr>
</tbody>
</table>

**Reader’s note**

For cable lengths for SIMODRIVE POSMO SI/CD/CA, refer to

**Reference:** /POS3/ User Manual SIMODRIVE POSMO SI/CD/CA
2.1.2 Mounting and installing the modules

When mounting and installing the SIMODRIVE modules on the rear cabinet panel, proceed in the following sequence:

1. Screw-in the retaining screws up to a clearance of approx. 4 mm from the surface of the mounting panel.
2. Locate the modules in the screws and then tighten the screws with 6 Nm.
3. Locate the DC link connecting bar in the adjacent module under the screws provided and tighten these screws with 1.8 Nm –0/+30%.

The DC link covers must only be installed with the power turned off. Check the spring elements for exact positioning prior to installation. Covers with warped spring elements must be replaced.

Drive bus

For drives with a digital setpoint interface, a drive bus cable is required for the control and communications interface SINUMERIK 840D powerline (refer to Fig. 2-1).

Table 2-1 Order number assignment

</tbody>
</table>

Equipment bus

The electronics power supply between the individual modules is established using the equipment bus cable (refer to Fig. 2-1). The equipment bus cable is included in the scope of supply of the power module.
2.2 Ambient conditions

Note
The components are insulated in compliance with DIN EN 50178.

- Overvoltage category III for industrial line supplies
- Degree of pollution II, especially no conductive pollution, moisture condensation is not permissible
- Installation altitude up to max. 2000 m above sea level
- Installation altitude 2000 m – 6500 m possible in conjunction with isolating transformer with neutral point on grounded the secondary side, grounded module housing.
- As a result of the "thinner air" (poor thermal dissipation), above 1000 m, the drive power must be derated (reduced). Refer to Chapter 6.4 and 5.4.
- Star point of the line supply is directly grounded, the module housing is grounded.

According to EN 61800–5–1 and UL 508 only protective extra low voltages with safety separation may be connected at all connections and terminals of the electronic modules.

Warning
Any conductive dirt/pollution can result in the safe electrical separation being lost and can therefore result in hazards to personnel (electric shock).

Note
Appropriate measures (filter, waiting cycles, etc.) must be adopted to prevent contamination of the cooling system, because otherwise fan damage and thus loss of the cooling effect can occur.

1) Supplementary measure is required, if the work to be carried out close to the DC link busbar (DC link cover at the last module).

2) Test values shall not be permitted as a permanent load.
2.3 Motor selection

Selection

The Motor Configuration Manuals are used to select the drive motors.

Reader's note

You can find information on the following motors under the following link:

- Ordering documentation/overview of documents
  - → Printed documentation → Docu_SIMOTICS
  - → DoConCD/User Manual Collection
- Links to download documents
  → Download documentation → SIMOTICS S servomotors
  → SIMOTICS M main motors
- Using documentation online (finding and searching in manuals/information)
  http://www.siemens.com/motioncontrol/docu

The selection of the motor and the (brief) overload capability determines the size (rating) of the power module (refer to Chapter 4).

VP module (VPM)

A voltage protection module (VPM) is required for motors 1FE1 and 2SP1 with an EMF > 800 V and maximum < 2 kV (> 565 V<sub>eff</sub> up to a maximum 1400 V<sub>eff</sub>). When a fault condition develops, the VPM limits the DC link voltage at the drive converter.

Technical data and ordering data, refer to 8.16.

/ PJFE/ Configuration Manual, 1FE1 Synchronous Built–in Motors 
/ BU/ Catalog NC 60 
/ PMS/ Configuration Manual ECO Motor Spindles for 2SP1 Main Spindle Drives
2.4 Position sensing/actual speed value sensing

Description

The encoder system is used for precise positioning and to determine the actual speed value of the drive motor for the particular application. The resolution of the measuring system and the control board selected are decisive when it comes to positioning accuracy.

2.4.1 Position sensing, direct

Measuring systems that can be evaluated

- Rotary encoders with sine/cosine–shaped voltage signals.
- Linear scales with sine/cosine–shaped voltage signals.
- Distance–coded measuring systems (only SIMODRIVE 611 digital with NC)
- Measuring systems with sine/cosine–shaped voltage signals and EnDat/SSI interface (linear scales, singleturn and multturn encoders)

The feed and main spindle drive modules can be supplied with a second measuring system evaluation, e.g. for a table–top measuring system or for spindle position sensing. A direct measuring system is needed, for example, when a high degree of accuracy has to be achieved on the workpiece with a linear scale or exact positioning is required with a multi–stage gear unit.

SIMODRIVE 611 digital, universal

The optimum measuring system for position detection is suitable for the evaluation of incremental encoders with sine/cosine voltage signals. It is possible to connect linear scales and rotary encoders with sinusoidal voltage signals to drive controls to operate 1FT6 and 1FK6 feed motors. The measuring signals supplied by the encoder system are evaluated with a high degree of resolution.

Example:

With a linear scale (20 µm grid constant) a position resolution of 0.01 mm (Digital High Performance control) is achieved.
2.4.2 Position detection, indirect

Measuring systems that can be evaluated

- Integrated incremental encoder in feed and main spindle motors
- Integrated absolute encoder with EnDat interface in feed motors
- Incremental encoder (SiMAG H) for sensing the rotary angle and the rotary angle velocity

SiMAG H is used for hollow-shaft applications with 1FE1 and 1PH2 direct drives and third-party spindles. It is also used as autonomous spindle encoder.

Reader’s note
Reference: /PMH/ Measuring System for Main Spindle Drives

SIMODRIVE 611 digital/universal

When the SINUMERIK 810D/840D and SIMODRIVE 611 are digitally linked, the measuring systems are connected to the digital control units.

The controls are equipped by default with a connection for the measuring system integrated in the feed and main spindle modules. Together with the high resolution position detection of the digital controls, the integrated motor measuring system achieves a resolution of 4,000,000 increments per revolution (Performance Control). In many cases, also for the main spindle, it means that an additional C-axis encoder is not required.

The high-resolution actual position value is also transferred to the NC position control loops via the drive bus so that, given the right mechanical conditions, a direct table-top measuring system is no longer required.

The same secondary conditions/limitations apply for SIMODRIVE 611 universal and POSMO SI/CD/CA. The only difference is the drive link established using PROFIBUS DP.
2.4.3 Drive module

The drive modules comprise the following components: Power module, control unit, equipment bus cable and where relevant, a drive bus cable and option module.

The permissible combinations of power module and control unit are saved in the engineering tables (refer to Chapter 1.3.5). Depending on the cooling method employed or the power module’s size, additional cooling components have to be ordered or be provided by the user.

Depending on the application, the drive modules of the SIMODRIVE 611 converter system can function as feed, main spindle or induction motors, and comprise the power module, control unit, and drive bus cable components. Option modules can be added where applicable.

A drive module is created by inserting the control unit into the power module, e.g. for feed or main spindle applications.

The modular design of the drive modules allows a large number of applications to be implemented using only a small number of individual components.

Note

Combinations that differ from the engineering information and instructions – where relevant, also in conjunction with third–party products, require a special, contractual agreement.

We accept a warranty for our scope of supply up to the system interfaces that we have defined.

2.5 Power modules

A wide range of 1–axis or 2–axis power modules is available. These modules are graded according to the current ratings and can be supplied with three different cooling techniques. The range of power modules allows a seamless, modular and space–saving drive solution for:

- Small, compact machines (required feed torques and main spindle power ratings – e.g. 80 Nm at 500 RPM and 11 kW S1 at 1500 RPM) up to
- complex machining centers and automatic lathes – e.g. 115 Nm or 145 Nm at 2000 RPM and 100 kW S1 at 1500 RPM.

The current–related data refers to the series–preset values. The output currents can be limited by the control unit being used. After the control unit has been inserted, the retaining screws of the control unit front panel must be tightened in order to establish a good electrical connection to the module housing.

At higher clock cycle frequencies, ambient temperatures and installation altitudes above 1000 m above sea level, the modules must be derated. The appropriate pre–assembled cables are available to connect–up the motors. The ordering data is provided in Catalog NC 60, in the Motors Section.

Shield terminal plates are available to meet EMC requirements when using shielded power cables.

The equipment bus cable is included in the scope of supply of the power module. The drive bus cables must be ordered separately for the digital system.
### 2.5 Power modules

#### 2.5.1 Function of the power modules

The power module provides the required energy for the control boards and the connected motor. The power module is selected depending on the selected motor and the control board.

#### 2.5.2 Connecting–up the power modules

The power module is grounded through the PE connecting screws.

The power module must be mounted on a grounded, low–resistance conductive mounting surface and must have a conductive connection to this mounting surface.

Power is fed–in through the DC link busbars.

![Power module with control unit](image-url)
2.6 Control units

2.6.1 General

The SIMODRIVE 611 control units use the power module to control the speed, torque and position of the attached motors. (Properties, for details refer to the module description in Chapter 4)

2.6.2 AC motors

The following AC motors, for example, can be operated synchronously or asynchronously:

- 1FT/1FK servo motors
- 1PH/1PM induction motors
- 1FE1/2SP1 built-in spindle motors
- 1 FW torque motors
- 1 FN linear motors
- Third-party motors (when suitable!)

2.6.3 Modules included in the scope of supply

For SINUMERIK 840D powerline

- High Performance as 2-axis or 1-axis control unit, optionally also with direct measuring system.
- High Standard as 2-axis control unit, optionally also with direct measuring system.
- HLA/ANA as 2-axis control unit for highly-dynamic "hydraulic axes" (modulating valves) or universal dynamic "analog interface" for components to be controlled externally.

For universal applications

- SIMODRIVE 611 universal in the system group or also for "standalone" devices.
  Various variants with analog or PROFIBUS DP interface. Variants with or without integrated positioning.
- SIMODRIVE 611 universal HRS / HRS2 with Resolver as 2-axis or 1-axis control unit.
- SIMODRIVE 611 universal HRS (high resolution) as 2-axis control units for encoders:
  - sin/cos or
  - EnDat or
  - TTL (only induction motors)
### 2.6 Control units

**For SINUMERIK 840Di powerline**  
**SINUMERIK 802D**

- SIMODRIVE 611 universal E HRS (economic high resolution) as 2-axis control units for encoders:
  - sin/cos or
  - EnDat or
  - TTL (only PROFIBUS DP interface for the controller)

- Encoder characteristics: "~3dB cutoff frequency" greater than or equal to 500 kHz  
  Examples for permissible encoders: ERA 180 with 9000 pulses/revolution and ERA 180 with 3600 pulses/revolution manufactured by Heidenhain  
- Amplitude monitoring up to 420 kHz is active.
2.6.4 NCU box for SINUMERIK 840D

If the digital drive modules are operated in conjunction with the SINUMERIK 840D CNC control system, then the NCU box must be located immediately to the right of the infeed module.

![Digital closed-loop control with SINUMERIK 840D](image)

Fig. 2-5 Digital closed-loop control with SINUMERIK 840D
2.7 Infeed modules

Application

The infeed modules are used to connect the drive group to the line supply.

The infeed modules generate the DC voltage for the DC link from the following possible line supply voltages:

- 3–ph. 400 V AC ± 10% 50 Hz/60 Hz,
- 3–ph. 415 V AC ± 10% 50/60 Hz,
- 3–ph. 480 V AC + 6% –10% 50 Hz/60 Hz

In addition, the electronic voltages (± 24 V, ± 15 V +5 V, etc.) are made available centrally to the drive modules and to the SINUMERIK 840D or SINUMERIK 810D – arranged as group – via the equipment bus.

Different line supply

If the infeed modules are connected to a line supply other than a TN line supply, or a line supply that is not equipped with suitable residual current protective devices, then an additional transformer with separate windings in vector group yn is required according to selection table 7-8.

The HF commutating reactor is also required for the regulated infeed/regenerative feedback module when there are upstream transformers.

An appropriate matching transformer is also required for line supply voltages of 3–ph. 200 V/220 V/240 V/440 V/500 V/575 V AC 10% 50 Hz/60 Hz.

Please observe the appropriate information and instructions for the 300 mm modules.

Module arrangement

For the arrangement of the infeed module, see Chapter 2.1.1.

A minimum lateral clearance of 50 mm must be maintained between the module groups mounted at the same height.

Heat dissipation

The necessary cooling components, such as externally mounted fan and/or air baffle plates for a module width of 100 mm to guide the air at the module heat sinks must be separately ordered when required. For other module widths, the baffle plates should be appropriately produced according to the drawing, see the dimension drawing in Chapter 12.

- Internal cooling
  
The infeed modules can be ordered with module–internal heatsinks for cooling inside the control cabinet. The 300 mm wide modules, that can be ordered for pipe cooling, also offer the option of connecting a pipe for direct air cooling.

- External cooling
  
Alternatively, infeed modules with heat sinks outside the housing for external cooling are available. When mounting, the heatsinks are inserted through the openings at the rear of the cabinet. Cooling is then realized on the customer side. For this type of configuration, a mounting frame is required for each module (refer to Fig. 2-9).
2 System Configuration

2.7 Infeed modules

Dimensions

All modules have a grid dimension of 50 mm for the width. All modules have a standard height of 480 mm. Note that the dimensions for air baffle plates, shield connecting plates, built–on fans and hose cooling must also be taken into account.

- Width: 50 mm grid dimension

- Relative to the mounting plane, the depth of all modules (without connectors and optional machine–mounted accessories) is:
  - Internal cooling or hose cooling: 288 mm
  - External cooling: 231 mm, in this case, the heatsink penetration depth must be taken into account for the cooling duct.
2.7.1 Cooling components

Depending on the cooling method used, additional fan units and fan components, specifically designed for the system, must also be ordered.

A differentiation is made between three different cooling types.

1. For internal cooling, the complete power loss remains in the electrical cabinet in the form of heat.

2. With external cooling, the power module power loss (thermal) is externally dissipated in the form of heat and the power loss of the control unit is internally dissipated in the form of heat.

3. For pipe cooling, version with 300 mm wide modules with internal cooling, the complete power loss in the form of heat is conducted to the outside using a pipe connected to the module.

The mounted fan is connected directly to the control cabinet line supply.

![Diagram of standard system design for 300 mm wide modules with mounted fan for internal cooling](image)

**Warning**

The fan may only be commissioned if it is electrically connected to the module housing (PE fan via module housing).

**Caution**

If the fan has an incorrect direction of rotation (see arrow) then cooling is not guaranteed!
2 System Configuration

2.7 Infeed modules

6SN1123–1AA02–0FA
(Order No. 6SN11 62–0BA03–0CA1)

Fig. 2-7 System configuration with hose cooling (only for 300 mm wide modules)

The 2–tier design with pipe cooling is only permissible for the combination of modules, order no. 6SN1145–1BB00–0DA at the top and 6SN1123–1AA02–0FA at the bottom.

Note
DC link connection, refer to Chapter 9.1.3.
For connection details for the DC link adapter set, refer to the dimension drawing in Chapter 12.
2.7.2 Internal cooling

Note
The power loss is dissipated in the cabinet and must therefore be taken into account when engineering/dimensioning the cabinet cooling.
2.7.3 External cooling

**Fig. 2-9** Power module with inserted control unit, external cooling

---

**Note**

Refer to Fig. 2-9 for the air flow direction and the dimension drawing in Chapter 12 for the ventilation space. The dimensions of the installation frame are presented in the dimension drawing in Chapter 12.

---

**Notice**

For external heatsinks and fans, a high degree of pollution restricts the module cooling. This can cause the temperature monitoring function in the power module to respond. The heatsinks and fans must be checked for accumulated dirt at regular intervals.

**Clean when required!**
For external cooling, the module heatsinks extend through the mounting plane in the electrical cabinet and can therefore dissipate power loss into an external cooling circuit.

The breakout in the mounting panel can be made for each module or also for a complete group of modules. For a breakout for the complete group of modules, the specific mounting frames for the modules should be used. For 300 mm wide modules, the appropriate mounting frame must be used (Order No.: 6SN1162–0BA04–0EA0). The dimension drawings for the breakouts are provided in Chapter 12.

The mounting frames should be installed from the inside of the cabinet or from the rear. This also then guarantees the necessary mounting surface for EMC.

Note
The dimensions of the recesses for the reinforcing ribs have different lengths. Ensure that the modules are mounted-installed in a standard way.

Seal
The reinforcing ribs of the mounting frames, that are rounded-off towards the rear, have seals on both sides. A sealant (e.g. Terostat–96 made by Henkel) must be used to seal the edges of the mounting frames in contact with the mounting panel. Degree of protection IP 54 is achieved when the sealant is correctly applied.

The fan cable must be fed into the electrical cabinet using a PG gland to ensure that the degree of protection is maintained.

The mounting panel must be sealed at the rear panel of the electrical cabinet so that a closed space or duct is created. Depending on how the cabinet is mounted (free-standing or installed in the machine), this must be cooled/ventilated via the roof/base assembly or the rear panel.

Make sure that the air inlet is unobstructed. The distance to the side walls must be at least 50 mm.

Fans must not draw in any air contaminated with cooling lubricant nor must they be sprayed with cooling lubricant, as this will considerably reduce their service life because of them sticking and cooling ducts can become clogged.

For further information refer to the device-specific technical user documentation.

Mounted fans for 300 mm wide modules
The fan cable must be fed into the electrical cabinet using a PG gland to ensure that the degree of protection is maintained.

The mounting panel must be sealed at the rear panel of the electrical cabinet so that a closed space or duct is created. Depending on how the cabinet is mounted (free-standing or installed in the machine), this must be cooled/ventilated via the roof/base assembly or the rear panel.

Make sure that the air inlet is unobstructed. The distance to the side walls must be at least 50 mm.

Fans must not draw in any air contaminated with cooling lubricant nor must they be sprayed with cooling lubricant, as this will considerably reduce their service life because of them sticking and cooling ducts can become clogged.

For further information refer to the device-specific technical user documentation.
3.1 Motor selection

The motor type should be selected according to the mechanical and dynamic requirements placed on the motor.

3.1.1 Motor protection

To protect the motors, the specified motor protection circuit breakers should be connected downstream, which only switch a signal contact when the motor has an overload condition.

If the motor is separated from the power module with the pulses enabled during operation, then there is the danger that the power module will destroy itself together with the control unit. Because of the harmonic oscillations in the current, set approx. 10% above the rated current!

Note

Notice for UL applications:

These devices are not provided with load and speed sensitive overload protection and thermal memory retention up on shutdown or loss of power (for details see NEC, article 430.126(A)(2).

Anyway, the drives provide signal inputs for motor temperature (see chapters 5.1 and 5.2) and output signals to indicate motor overload conditions (see chapter 6.1).
3.1.2 Motors with holding brake

Description
The holding brake mounted onto the motors is used to brake the motor when it is already at a standstill. In an emergency, it can also additionally reduce the braking travel. The holding brake is not an operational brake.

Notice
The motor holding brakes should only be actuated at standstill.
If the holding brake is operated during operation or while the motor is turning, this results in increased wear and shortens the lifetime of the holding brake. This is the reason that failure of the holding brake must already be taken into consideration when engineering the system. A hazard analysis must be performed.

Suspended (hanging) loads

Danger
Special attention and consideration must be given when holding brakes are used for suspended (hanging) loads (injury, crushing, possibility of death, machine damage) as this application represents a high potential hazard.

3.2 Motor encoder

General
The motors are equipped with various encoder systems to sense the rotor position and speed.

Reference: refer to Appendix B in the relevant Configuration Manual of the motors

The assignment of the SIMODRIVE units to the servo/main spindle motor types and encoder systems is shown in the Table 3-5.

Depending on the requirements, various types of encoder are used and processed in the appropriate modules:

- sin/cos 1 Vpp or EnDat encoder
- SSI encoder (only SIMODRIVE 611 High Performance, High Standard, HLA/ANA)
- Resolver (only SIMODRIVE 611 universal)
- TTL encoder (only SIMODRIVE 611 universal with induction motors)

Induction motors can also be operated without encoders.

The modules provide high encoder resolutions with internal pulse multiplication.
The following encoder signals are recommended for fault–free operation:

- For track signals A+, A–, B+, B–, C+, C–, D+ and D–

![Signal characteristics for track signals A+, A–, B+, B–, C+, C–, D+ and D–](image1)

- For zero pulse/reference signal R+ and R–

![Signal characteristics for zero pulse/reference signal R+ and R–](image2)

If other encoder signals are used or in the case of TTL encoders, encoder signal monitoring can be triggered. In particular, the lower signal level for reference signals R+ and R– must be carefully observed.
3 Motor Selection, Position/Speed Sensing

3.2 Motor encoder

**Resolver**

Key data for resolver as motor encoder:

- **Pin assignment:** in accordance with Chapter 4.3.2, Table 4-13
- **Number of pole pairs:** 1 or equal to the pole-pair count of the motor
- **Resolver excitation:**
  - **HRS:** the control unit produces the voltage with 4.3 V\(_{\text{RMS}}\) at 9.6 kHz
  - **HRS2:** the control unit produces the voltage from approx. 0.98 V\(_{\text{RMS}}\) to 2.6 V\(_{\text{RMS}}\) (As a function of the transmission ratio of the resolver)
- **Nominal input voltage of the controller:**
  - **HRS:** sin/cos 2.0 V\(_{\text{RMS}}\)
  - **HRS2:** sin/cos 1.2 V\(_{\text{RMS}}\)
- **Transmission coefficient of the resolver:**
  - **HRS:** approx. 0.46 at 9.6 kHz
  - **HRS2:** approx. 0.46 at 9.77 kHz
    (often described with 1:2 transformation ratio in the datasheets)
- **The resolver excitation:**
  - **HRS:** is controlled within the control range to provide the input voltage of 2.0 V\(_{\text{RMS}}\).
  - **HRS2:** is set step-by-step within the setting range during module power-up to produce an input voltage of approx. 1.0 Vrms to 1.4Vrms.
- **Maximum excitation current:**
  - **HRS:** 28 mA\(_{\text{RMS}}\)
  - **HRS2:** 28 mA\(_{\text{RMS}}\)
    (corresponds to the minimum magnitude of 154 Ω of the complex input impedance of the resolver)

**Note**

The named key data represent starting values for the selection of the resolver but not a complete specification of the resolver interface. In specific cases, the user must check whether the chosen resolver in the complete system meets the requirements.
3 Motor Selection, Position/Speed Sensing

3.2 Motor encoder

- Encoder sin/cos 1 Vpp
  - “High Performance” and SIMODRIVE 611 universal control units can be parameterized for encoders up to 65,535 incr./rev. The increment value is increased by the factor 2048 using pulse multiplication in the evaluation of the modules. Encoders with 2048 incr./rev. are used in preference. The resolution is then approx. 4.2 million incr./rev. An increment then represents on a 10 mm spindle \( (10 \text{ mm}/(2048 \cdot 2048)) = 2.4 \text{ nm} \).
  - This means the “High Standard” control unit with a pulse multiplication of 128 with the standard encoder would then be resolved theoretically up to \( (10 \text{ mm}/2048/128) = 38 \text{ nm} \) with the 10 mm spindle.
  - For direct measuring systems (internal pulse multiplication also 2048), an encoder pulse number up to 32 bits can be set.
  - Linear scales can be parameterized with grid divisions from 0 to 8,388,607 nm. Linear encoders with 20 \( \mu \text{m} \) grid division are used primarily; the resolution is then \( (20 \mu\text{m}/2048) = 10 \text{ nm} \).
  - The encoder limit frequency \( f_G \), with sin/cos 1 Vpp encoders, for “High Performance” and SIMODRIVE 611 universal control units can be as high as 350 kHz, with secondary conditions up to 420 kHz, and max. 200 kHz for “High Standard” control units.
  - The “High Standard” control unit with the standard encoder permits max. 200 kHz \( (60\text{s}/2048) \) up to 5,660 RPM.
  - Linear encoders (20 \( \mu \text{m} \) grid) permit speeds with 350 kHz \( (20 \mu\text{m} \cdot 60\text{s}) \) up to 420 m/min.

- Resolver
  - The SIMODRIVE 611 universal control unit in the variant with resolver (1 – 6 pole pairs) permits resolutions with 12– or 14–bit and encoder limit frequencies up to 432 Hz or 108 Hz.
    HRS2: 957 Hz or 479 Hz
  - For a resolver with 1 pole pair, 12– or 14–bit achieves the resolution 4,096/rev. or 16,384/rev. namely 4,096 incr./rev. or 16,384 incr./rev.
  - The position resolution with 10 mm spindle pitch corresponds theoretically to 2.5 \( \mu \text{m} \) or 0.6 \( \mu \text{m} \). The values are correspondingly more favorable for resolvers with a higher number of poles, e.g. for six pole pairs.
  - Maximum speeds
    HRS: can be achieved with 12 bits and for pole pair 1 to 432 \( \cdot \) 60 = 26,000 RPM and with 14 bits up to approx. 6,500 RPM.
    HRS2: can be achieved with 12 bits and for pole pair 1 to 957 \( \cdot \) 60 = 57,420 RPM and with 14 bits up to approx. 28,740 RPM. Resolvers with a larger number of poles, e.g. six pole pairs, permit only correspondingly lower speeds.

Note

Because encoder systems (as result of excitation frequency, excitation amplitudes, windings, non–symmetry of the poles) can exhibit relatively high tolerances in the evaluation for analog/digital conversion, the actually achievable values are significantly lower in practice.
3 Motor Selection, Position/Speed Sensing

3.2 Motor encoder

- Encoder with TTL signal

  For the speed control of induction motors with SIMODRIVE 611 universal HRS control units, sin/cos 1 Vpp variant, TTL encoders can be connected and evaluated.

  The limit frequency $f_G$ can be as high as 420 kHz.

  The SIMODRIVE 611 universal E HRS control unit allows only one TTL signal to be passed to a higher level controller using the PROFIBUS DP.

---

**Note**

The actually achievable system quality with regard to speed or positioning accuracy depends primarily on the quality of the used encoders and other influencing factors, such as:

- the mechanical system (rigidity, backlash, mass ($GD^2$)), and also
- the control–engineering configuration of motors, power, controller (interpolation and control cycles, control parameters, etc.)

In practice, the previously mentioned effects mean the quality that can be achieved in a real system is significantly lower than the theoretically achievable quality.
3.3 Indirect position and motor speed sensing

The various possibilities for indirect position and speed sensing and to position the motor shaft as a function of the drive configuration (SINUMERIK, SIMODRIVE and Motor) are shown in Table 3-6 (Chapter 3.5).

3.4 Direct position sensing

3.4.1 Encoder systems that can be evaluated

The various possibilities for direct position sensing for positioning as a function of the drive configuration (SINUMERIK, SIMODRIVE and Motor) and the encoder system being used are shown in Table 3-7 (Chapter 3.5).

As a result of the higher data transfer reliability, we recommend that sinusoidal voltage signals are used.

The following encoder signals are recommended for fault–free operation:

- refer to Chapter 3.2 "Motor encoders"

Machine data MD 1326: $MD_SAFE_ENC_FREQ_LIMIT can be used to parameterize a limit frequency. The maximum value is 420 kHz, the lower limit and default value is 300 kHz.

Note

Changes to this MD may only be made carefully taking into account the prevailing conditions.
This functionality is only supported by SIMODRIVE 611 digital High Performance control units.

The following secondary conditions/limitations are specified:

1. Cable to be used:
   Siemens cable, Order No.: 6FX2002–2CA31–1CF0
2. Maximum permissible encoder cable length:
   Encoder limit frequency 420 kHz: 20 m
3. Encoder characteristics: “~3dB cut–off frequency” greater than or equal to 500 kHz
   Examples of encoders that can be used:
   ERA 180 with 9000 pulses/rev and ERA 180 with 3600 pulses/rev from the Heidenhain Company.
4. The amplitude monitoring that is active up to 420 kHz.
Incremental systems with two sinusoidal voltage signals A, B offset by 90 degrees (several, for distance-coded systems) reference mark(s) R.

Transfer: Differential signals
- A, *A; B, *B and R, R*

Amplitude A – *A 1 Vpp +20% –25%
Amplitude B – *B 1 Vpp +20% –25%
Amplitude R – *R 0.2 Vpp ... 1 Vpp

Power supply: 5 V ±5% (also refer to Chapter 3.4.2 Encoder power supply)

Max. power supply current: 300 mA
Max. processable enc. signal frequency: 200 kHz standard module/
420 kHz (as of SW 5.1.14)\(^1\) 350 kHz

Note

For the above specified max. encoder signal frequency, the signal amplitude must be \(\geq 60\%\) of the nominal amplitude and the deviation of the phase shift from the ideal 90° between track A and B must be \(\leq 30°\).

Observe the frequency characteristic of the encoder signals.

Incremental signals with two square wave signals A, B offset by 90 degrees and reference mark(s) R SIMODRIVE 611 universal HRS/
SIMODRIVE universal HRS E

Transfer: Differential signals

Signal level: According to RS422

Power supply: 5 V ± 5% (also refer to Chapter 3.4.2
Encoder power supply)

Max. power supply current: Max. 300 mA

Max. encoder signal frequency that can be evaluated: 420 kHz

Note
For the above specified max. encoder signal frequency, the edge clearance between track A and B must be ≥ 200 ns.

Observe the frequency characteristic of the encoder signals!

Fig. 3-5 Signal characteristic for a clockwise direction of rotation
3 Motor Selection, Position/Speed Sensing

3.4 Direct position sensing

SSI encoder

The SSI encoder is used as direct position measuring system (NC) (SSI scale/encoder is attached to the load). In addition to this direct position measuring system, on the motor side, the speed is sensed using an incremental motor encoder.

The exception is the measuring system sensing for SIMODRIVE 611D HLA, where the linear scale can be used as “motor measuring system”.

The used SSI encoders must comply with the following specification:

Gray or binary–coded encoders can be used under the assumption:

- Error bit/alarm bit is the LSB; if, in addition, a parity bit is transferred, then this is the next to last bit. If an alarm bit is not transferred, then the parity bit is the LSB.
- The net (useful) information – also as parity or error bit/alarm bit – are either gray or binary–coded – but never mixed.
- Message frame length (including alarm and/or parity):
  - SIMODRIVE HLA 13 and 25 bit,
  - SIMODRIVE 611D from 13, to 25 bit
- Data format: SIMODRIVE HLA only right justified
- For HLA: The encoder zero point of the linear encoder (absolute value 0) must not be located in the traversing range.
- Transfer frequency, $f$: 100 or 500 kHz.
- Monoflop time:
  - at 100 kHz $t_m \leq 12 \mu s$,
  - at 500 kHz $t_m \leq 2.4 \mu s$,
  - or $t_m > 1.2 \cdot 1/f$
- Operation is only possible without Safety Integrated!

Note

Only SSI encoders without incremental tracks may be used. The connection of SSI encoders is not possible on the connection for the indirect measuring system (X411, X412). The use as direct measuring system is possible only for HLA axes.
3.4.2 Encoder power supply

Remote/sense operation is possible with the encoder power supply for the motor measuring systems and the encoder power supplies for the measuring systems for direct position sensing (voltage controlled directly on the encoder to ±5%).

Remote/sense operation means:

The power supply voltage of the measuring system is sensed using the sense lines P sense and M sense (quasi zero–current measurement).

The controller compares the measuring system power supply voltage, sensed using the remote sense lines, with the reference power supply voltage of the measuring system and adjusts the power supply voltage for the measuring system at the drive module output until the required power supply voltage is set directly at the measuring system.

This means that the voltage drops across the power supply cables – P encoder and M encoder – are compensated and corrected by the encoder power supply.

The reference voltage is generated from a reference voltage source and is 5 V.

This means that it is possible to use cable lengths up to 50 m without having to operate the measuring systems with an undervoltage condition.

Note
All data only apply for SIEMENS pre–assembled cables as these are correctly dimensioned regarding the cable cross–sections.

For SIMODRIVE connection systems and also for the measuring system suppliers, remote/sense operation is only possible for encoder systems with voltage signals.

For motor measuring systems and mounted SIMODRIVE sensor encoders, the sense lines are connected in the encoder or in the connector on the encoder side. For third–party encoder systems, the customers must make the appropriate connections.

High Performance digital FD and MSD drive control

Remote/sense operation

![Signal overview of the connections](image)

Fig. 3-6 Signal overview of the connections
3.4.3 Encoder power supply for SSI encoders

General information

For SIMODRIVE, an internal 5 V is provided to supply encoders. When using SSI encoders, the power supply voltage must be externally connected to the encoder cable.

What has to be observed?

The following must be observed (refer to Fig. 3-7):

Note

SSI encoders are likely to have lower noise immunity due to the encoder and the 24 V power supply.

- The encoders must be supplied with a separately regulated 24 V voltage (e.g. SITOP power) in order to avoid disturbances/noise due to contactors, etc.
- The external 24 V power supply must have “safe separation” (PELV/SELV).
- Filter data:
  - The special filter is required in order to filter-out noise and disturbances
  - Maximum continuous operating current = 0.8 A (use a fuse!)
  - Max. voltage = 30 V
  - One filter is designed for two encoders with a maximum current = 0.4 A
- The 24 V supply (reference potential) should be connected to the electronics ground of the system (e.g. terminal X131 on the NE module) if this connection is not already provided in the encoder.
- Maximum cable length between the 24 V supply and the filter 10 m
- Maximum encoder cable = 40 m
- The technical data of the encoder manufacturer must be carefully observed.
- Third-party encoders must be connected using the adapter cables provided by the particular manufacturer.

3.4.4 Signal amplifier electronics

The signal amplifier electronics (SVE) is used for encoders with current signals between the encoder and drive module to convert the current signals into voltage signals 1 Vpp.

The signal amplifier electronics were developed for optical encoder systems equipped with photodiodes and no additional supplementary electronics (example, ROD 456 from the Heidenhain company). However, there are many encoder systems in the market with integrated electronics where the behavior of current signals is only roughly emulated. As a result of the many options available, a general statement regarding the compatibility between the encoder, SVE and closed-loop control cannot be made.

Notice

For new applications, no longer use encoders with current signals, as voltage signals offer a higher noise immunity.

The signal amplification electronics can be used in conjunction with the following control modules:

- SIMODRIVE 611 digital High Standard or High Performance
- SIMODRIVE 611 universal HRS/E HRS for encoders with sin/cos 1Vpp
- HLA module
- ANA module

1) The absolute accuracy for so-called synchronization with a BERO depends on the following:
- the switching time of the BERO
- the hysteresis of the BERO
- the signal edge gradient (rate-of-rise) of the BERO signal (depending on the direction of rotation) and the switching thresholds in the drive; high > 13 V, low < 5 V
- the search speed and the signal runtimes in the evaluation electronics

2) Distance-coded reference marks can be evaluated

4.1  Closed–loop control with digital setpoint interface

Digital control units in 1–axis and 2–axis versions (for 1PH, 2–axis control is only possible with High Performance) are available to operate motors 1FT6/1FK/1FN1/1FN3/1FE1/1PH/1PM/1FM6/2SP1.

During the initialization phase (power on or reset), the drive software is downloaded from the SINUMERIK 840D to the control board via the drive bus.

High Performance: Order No.: 6SN1118–0DJ2–0AA

The digital 1–axis High Performance control can be loaded with the drive software for either FD control or MSD control. MSD and FD have the same user interface. The board is available in the following versions:

- Basic version with sinusoidal voltage signals and the possibility of connecting absolute encoders with EnDat interface
- In addition, the evaluation of a direct position measuring system with sinusoidal voltage signals and the connection of absolute encoders with EnDat interface and SSI interface (as of SW 5.1.9) is possible.

High Standard: Order No.: 6SN1118–0DM3–0AA

The module is available in three basic versions that differ in the controller performance and in the evaluation of the direct position measuring systems:

- Basic version with sinusoidal voltage signals and the possibility of connecting absolute encoders with EnDat interface
- Additionally with evaluation for 2 direct measuring systems with sinusoidal voltage signals and the possibility of connecting absolute encoders with EnDat interface and SSI interface (from SW 5.1.9).

Note

A 2–axis drive control can also be operated in a single axis power module for single axis applications. It is engineered as a 1–axis board.

For motor encoders without any adjustment to the EMF of the synchronous motor (1FE1/1FN1/1FN3) a configurable, automatic identification technique can be used to determine the electrical rotor position. In so doing, motion of typically <±5 degrees mechanical is not exceeded. The identification routine is performed after each power up operation.

4.1 Closed–loop control with digital setpoint interface

**Notice**
When using non–PELV/SELV circuits at terminals AS1, AS2, connectors must be coded to prevent the connectors being incorrectly inserted (refer to EN60204–1, Section 6.4).
For Order No. for coded connectors, refer to Catalog NC 60.

**Warning**
At terminals 19, P24 and M24, only PELV/SELV circuits may be connected. If this is not carefully observed, then this can result in personal injury in the form of electric shock.
Notice
When using non-PELV/SELV circuits at terminals AS1, AS2, connectors must be coded to prevent the connectors being incorrectly inserted (refer to EN60204–1, Section 6.4).
For the order number for coded connectors, refer to Catalog NC 60.

Warning
At terminals 19, P24 and M24, only PELV/SELV circuits may be connected. If this is not carefully observed, then this can result in personal injury in the form of electric shock.

| X141/341  |            | Drive bus | For the terminal assignment, refer to Table 4-6 |

1) I=Input; O=Output; NC=NC contact; NO=NO contact (for a signal, NO=High/NC=Low)
2) The terminal may only be used to enable the associated drive group.
3) When connecting contacts AS1/AS2 in series, a contact voltage drop up to max. 0.2 V must be taken into account for the lifetime of the contacts (100000 switching operations). For a 24 V switching voltage, due to the non-linear contact characteristics, from experience, five contacts can be simply connected in series without encountering any problems.
4) A UL–certified miniature fuse (max. 3.15 A) must be provided at the supply for the brake control:
   Value: e.g. 3.15 AT/250 V; 5x20 mm UL
   From: ekontor GmbH
   Uhdestraße 31–33
   D–74006 Heilbronn
   or
   Postfach 1661
   D–74006 Heilbronn
   Order No.: Littlefuse 021602.5TXP
5) In order to increase the strength with respect to surge disturbances, for encoder cables > 30 m long, the screen connection 6SN1162–0FA00–0AA2 can be used. In order to ensure noise immunity in compliance with the standard, the encoder cable shields should be connected where the cable enters the control cabinet.
   The permissible voltage range for the common mode component of the individual encoder signals (A+, A–, B+, B–, C+, C–, D+, D–, R+, R–) is 1.5...3.5 V.
6) According to EN 60204–1 (Safety of Machinery) control transformers should be used when using AC control voltages.

</tbody>
</table>

Note:
The inputs on the control must not be assigned any signals other than the intended signals. Otherwise, sporadic or permanent malfunction or damage can occur. In particular, any existing signals of additional temperature sensors (PTCs, NTCs, etc.) for spindle applications must NOT be applied to the unused CP, CN, DP, or DN inputs when using induction motors!

<td>Inverse clock signal, EnDat interface</td>
<td></td>
</tr>
</tbody>
</table>

**Note:**
The inputs on the control must not be assigned any signals other than the intended signals. Otherwise, sporadic or permanent malfunction or damage can occur. It is especially important for spindle applications, that possibly available signals from additional temperature sensors (PTCs, NTCs or similar) must NOT be connected to the CP–, CN–, DP–, DN inputs that are not used when using induction motors!

When "parking axis" is selected, the encoder can be withdrawn and inserted also under voltage.

1) I: Input; O: Output
4.3 “SIMODRIVE 611 universal HRS” and “HRS2” (from SW version 14.2) control board

Description
The "SIMODRIVE 611 universal HRS" control board is used in the SIMODRIVE 611 system (SW > 8.3) and includes two drive controls that are independent of one another. However, the board can also be used for 1–axis applications and in 1–axis power modules.

Note
The control board is described in detail in:

References: /FBU/ Description of Functions, SIMODRIVE 611 universal

The functionality specified in this Description of Functions under "SIMODRIVE 611 universal" also applies to "SIMODRIVE 611 universal HRs" and "HRS2".

Features
The control board has the following features:

- Variants

¹) For 2–axis control boards, 1–axis operation is also possible
²) Space retainer for software version
³) Prerequisite: Control board as of SW 3.1
4 Control Units

4.3 “SIMODRIVE 611 universal HRS” and “HRS2” (from SW version 14.2) control board

- Settings
  All drive–related settings of the control board can be made as follows:
  - Using the SimoCom U parameterizing and startup tool on an external PG/PC
  - Using the display and operator control unit on the front panel
  - Using PROFIBUS DP (parameter area, PKW area)

- Software and data
  The firmware and the user data are saved on a memory module which can be replaced.
  The software designation on the memory module refers to the system software including the initial program loader.

- Terminals and operator control elements
  - 2 analog inputs, 2 analog outputs per drive
  - 4 digital inputs, 4 digital outputs per drive
  - 2 measuring sockets
  - POWER–ON RESET pushbutton with LED
  - Display and operator unit

Warning
When handling the operating unit or an interface for an external PG/PC (X471, X423 on the Profibus option) protective measures must be taken against electrostatic discharge:
- Working with a grounded ESD wristband or
- Wearing ESD shoes in connection with ESD flooring.

Safe start inhibit
The start inhibit is addressed via terminal 663 and is signaled back using a relay with positively–driven signaling contacts (AS1/AS2). Using the start inhibit, the energy feed from the drive to the motor is interrupted.
When the "safe start inhibit" function is correctly used, the signaling contacts AS1/AS2 must be included in the line contactor circuit or the EMERGENCY OFF circuit.

Caution
When using the "safe start inhibit" function, it must be ensured that the velocity goes to zero.

The "SIMODRIVE 611 universal HRS / HRS2" control board supports the "Safe standstill" function.
Detailed information about the "safe standstill" function is provided in Chapter 8.5.
4.3 "SIMODRIVE 611 universal HRS" and "HRS2" (from SW version 14.2) control board

- Serial interface (RS232/RS485)
- Option modules
  - Optional TERMINAL module, 8 digital inputs and 8 digital outputs for drive A
  - Optional PROFIBUS–DP module
- Expanded functions as of SW 5.1
  The following expanded functionality is provided with a new control board for sin/cos 1Vpp encoders:
  - Higher internal resolution, interpolation factor 2048 (previously 128)
  - Pulse multiplication is possible (doubling) at the angular incremental encoder interface for absolute encoders
  - Pulse multiplication (doubling) and division (1:2, 1:4, 1:8) are possible at the angular incremental encoder interface, also for incremental encoders
4.3.1 Control board for 1 or 2 axes

The following 2-axis control boards are available:

- Mounting slot for
- Optional TERMINAL module
- Optional PROFIBUS DP module
- Interfaces
- Terminals
- Switches
- Memory module
- Firmware
- User data
- Display and operator unit
- Pulse interface
- Equipment bus

The following applies to retaining screws:

Tighten (to establish a good shield contact)
max. torque = 0.8 Nm

For plug connections:

Plug connectors with the same number of pins must be appropriately coded so that they cannot be interchanged (refer to the index entry "Coding the mini connectors").

Fig. 4-4 Control boards for 2 axes (SIMODRIVE 611 universal HRS / HRS2)
Control board for 1 axis

The following 1–axis control boards are available:

- These interfaces have no function for the 1–axis version

1. Mounting slot for
   - Optional TERMINAL module
   - Optional PROFIBUS DP module

2. Interfaces
   - Terminals
   - Switches

3. Memory module
   - Firmware
   - User data

4. Display and operator unit

5. Pulse interface

6. Equipment bus

The following applies to retaining screws:
Tighten (to establish a good shield contact)
max. torque = 0.8 Nm

For plug connections:
Plug connectors with the same number of pins must be appropriately coded so that they cannot be interchanged (refer to the index entry “Coding the mini connectors”).

Fig. 4-5   Control board for 1 axis (SIMODRIVE 611 universal HRS / HRS2)
**Optional terminal module**

An additional 8 digital inputs and outputs can be realized using this optional module.

The functionality of these inputs/outputs can be freely parameterized.

---

**Note**

- The input/output terminals of the optional TERMINAL module are
  - Before SW 4.1: permanently assigned to drive A or axis A
  - As of SW 4.1: can be freely assigned axes

- The optional TERMINAL module can be used as follows, dependent on the software release:
  - The following applies before SW 2.4:
    The module can only be used in the “positioning” mode.
  - The following applies as of SW 2.4:
    The module can be used independently of the operating mode.

---

**Order number:** 6SN1114–0NA00–0AA0

**Fig. 4-6  Optional TERMINAL module**

For screws:
- Tighten (due to the shield contact)
- max. torque = 0.8 Nm
4.3 “SIMODRIVE 611 universal HRS” and “HRS2” (from SW version 14.2) control board

Optional PROFIBUS DP module

The “SIMODRIVE 611 universal” control board can be connected and operated as DP slave on the PROFIBUS DP fieldbus when this optional module is used.

![Diagram](image)

Two-color LED for diagnostics

For screws:
Tighten (due to the shield contact)
max. torque = 0.8 Nm

Fig. 4-7 Optional PROFIBUS DP module

Table 4-8 Which optional modules are available?

<table>

</table>
| PROFIBUS DP2 | 6SN1114–0NB00–0AA2 | • PROFIBUS ASIC DPC31 without PLL  
• For control boards as of SW 3.1, this module can replace the optional PROFIBUS DP1 module |
| PROFIBUS DP3 | 6SN1114–0NB01–0AA1 | • PROFIBUS ASIC DPC31 with PLL  
• “Motion Control with PROFIBUS DP” function (clock-synchronous PROFIBUS operation) is possible |

Features that PROFIBUS DP2 and DP3 have in common

• Requirement: Control board as of SW 3.1 is required  
• Cyclic data transfer (PKW and PZD section) possible  
• FW module can be updated using SimoCom U  
• Non-cyclic data transfer (DP/V1)  
• “SimoCom U via PROFIBUS” possible
## Table 4-9 Which optional modules can be used for the various software releases?

**Note**

Case 1 is for "new" applications with the DP2, DP3 module.

Cases 2 and 3 are for series commissioning of drives using DP1 modules and for replacing a defective DP1 module by a DP2 module.
4.3.2 Description of the terminals and interfaces

Board–specific terminals and interfaces

The board–specific terminals and interfaces are available jointly for drive A and B of a 2–axis module.

Table 4-10 Overview of the board–specific terminals and interfaces

<table>

<td>S</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The external supply is required for the following digital outputs:
- 8 outputs of the optional TERMINAL module (X432, 04 – 011)

When dimensioning the external power supply, the total current of all of the digital outputs must be taken into account.

Maximum total current:
- for the control board (all 8 outputs): 2.4 A
- for the optional TERMINAL module (all 8 outputs): Max. 480 mA

Example:

<table>

<th>Type 1</th>
<th>Technical specifications</th>
</tr>
</thead>
</table>
| 9   | X431.3               | Enable voltage (+24 V) | S      | Reference: Terminal 19  
Maximum current (for the total group): Max. 500 mA  
Note:  
The enable voltage (terminal 9) can be used to supply the enable signals (e.g. pulse enable) as 24 V auxiliary voltage. |
| 663 | X431.4               | Pulse enable (+24 V)  | I      | Voltage tolerance (including ripple): 21 V to 30 V  
Typ. current consumption: 50 mA at 24 V  
Note:  
The pulse enable acts simultaneously on drive A and drive B.  
When this pulse enable is withdrawn, the drives “coast down” unbraked. |
| 19  | X431.5               | Reference (Reference for all digital inputs) | S      | Note:  
If the enable signals are to be controlled from an external voltage source, the reference potential (ground) of the external source must be connected to this terminal. |

Serial interface (X471)

| –   | X471                 | Serial interface for “SimoCom U” | IO     | Type: 9–pin D–sub socket connector  
Cable diagram and pin assignment for RS232 or RS485, refer to:  
Reference: /FB611U/ Description of Functions, SIMODRIVE 611 universal |

Equipment bus (X34)

| –   | X351                 | Equipment bus | IO     | Ribbon cable: 34–pin  
Voltages: various  
Signals: various |

Test sockets (X34)

| M   | DAC1                 | Test socket 1  
2)  | M      | Test socket: ⊙ 2 mm  
Resolution: 8 bits  
Rated operating voltage: 0 V to 5 V  
Maximum current: Max. 3 mA  
| –   | DAC2                 | Test socket 2  
2)  | M      |  |
| M   | Reference            | Reference     | M      |  |

1) I: Input; IO: Input/output; M: Measuring signal; NC: NC contact; S: Supply  
2) Can be freely parameterized  
3) When connecting contacts AS1/AS2 in series, a contact voltage drop up to max. 0.2 V must be taken into account for the lifetime of the contacts (100000 switching operations). For a 24 V switching voltage, due to the non–linear contact characteristics, from experience, five contacts can be simply connected in series without encountering any problems.  
4) In accordance with EN 60204–1 (machine safety) control–power transformers should be provided when AC control voltages are used.
### Drive-specific terminals

The drive-specific terminals are available for both drive A and drive B.

© Siemens AG 2014 All Rights Reserved

1) I: Input; DO: Digital output; DI: Digital input; AO: Analog output; AI: Analog input; S: Supply
2) Can be freely parameterized. All of the digital inputs are de-bounced per software. When detecting the signal a delay time of between 1 and 2 interpolation clock cycles (P1010) is therefore incurred.
3) I0.x is internally hard-wired to the position sensing and acts there with almost no delay.
4) Can be freely parameterized. The digital outputs are updated in the interpolation clock cycle (P1010). A hardware-related delay time of approx. 200 µs must be added.
5) The permissible voltage range for the common mode component of the individual encoder signals (A+, A-, B+, B-, C+, C-, D+, D-, R+, R-) is 1.5...3.5 V.

---

**Warning**

Only PELV/SELV circuits may be connected to terminals 19, 663, 65.A, 65.B, P24 and M24, I0.A...I3.A, I0.B...I3.B, terminals I4...I11 of the Option Module. Failure to do so can cause injury due to electric shock.

4.4 "HLA module" control board

Description

The hydraulics (HLA) module provides a means of controlling hydraulic axes directly from the SINUMERIK 840D system via the digital drive bus. The HLA module is a control unit belonging to the modular SIMODRIVE 611 converter system mounted in a 50 mm wide carrier module (universal empty housing). The gating and closed–loop control electronics for operating hydraulic drives are integrated in the HLA module.

The control unit can also be used as an ANA control unit for analog axes. This double–axis board can be used in mixed operation (HLA/ANA). Hydraulic drives have the same significance as electric drives also when combined within an interpolating group.

Note

The HLA module is described in detail in:

References:
/FBHLA/, SINUMERIK 840D SIMODRIVE 611 digital HLA module, Description of Functions

Features

The HLA module has the following features:

• Software and data
  
The communications interface is compatible with SIMODRIVE 611 SRM(FD)/ARM(MSD) for supported services. Code and data structure is analogous to SIMODRIVE 611 SRM(FD)/ARM(MSD). The hydraulics software is stored as a separate program code in the control system.

• Hardware
  
Integration into the SIMODRIVE 611 system is compatible with SIMODRIVE 611 digital SRM(FD)/ARM(MSD). Essentially, this involves the following interfaces:
  – Drive bus
  – Equipment bus
  – Power supply concept

• HLA control unit (2–axis)
  – Velocity pre–control, controller
  – Force control
  – Voltage output for actuators
  – Connection for two pressure sensors per axis
  – Control of hydraulic control valves

• Terminals and diagnostics
  – Control of a hydraulic shut–off valve
  – BERO input per axis
  – Module–specific enable signal
  – Test sockets (diagnostics)

Warning

Only PELV/SELV circuits may be connected to terminals 19, P24 and M24. Failure to do so can cause injury due to electric shock.
4.4.1 System overview

A complete SINUMERIK 840D with HLA module comprises of various individual components. These are listed below.

- MCP
- MMC CPU
- Equipment bus
- Battery and fan slot
- HLA module
- NCU
- Digital I/O (high-speed NC I/O)
- Measurement (2x)
- Handwheel (2x) (1x of M)
- Full CNC keyboard
- Cable distributor
- PCMCIA
- NCU box
- External 26.5 V supply
- SITOP power (external power supply)
- Line infeed
- NC CPU
- Cable distributor
- Modular control panel
- Operator panel
- Machine control panel
- HHU
- Distributor box
- Cable distributor
- External 26.5 V supply
- SITOP power (external power supply)
- Note: Hydraulics shown for one axis
- Modulating valve
- Shut-off valve
- Pressure sensor A
- Pressure sensor B
- Position sensing

Fig. 4-8 System components
4 Control Units

4.4 “HLA module” control board

Fig. 4-9 Connection configuration for HLA module
4.4.2 Wiring

Line supply connection

The SINUMERIK 840D and the HLA module are supplied from the SIMODRIVE line supply infeed or from the SIMODRIVE monitoring module via the equipment bus. There must be at least one NE module in the equipment group when an HLA module is used. No provision has been made for any other type of voltage supply and failure to use the supply provided could damage the unit.

Note

It is not permissible to operate an HLA module on its own with a SIMODRIVE monitoring module!

Power is supplied to downstream electrical axes via the DC link busbars (40 mm²) of the carrier module.

Measuring systems

One position encoder for each axis can be evaluated on the HLA module.

- X101: Axis 1
- X102: Axis 2

The measuring system must always be plugged into the connector of the associated axis.

</tr>
</tbody>
</table>

1) I = Input, O = Output

The analog valve actual value inputs are differential with 100 kΩ input resistance.

The current ratings of the 24 V outputs of the control valves are

- for an ambient temperature of 40 °C 2.0 A
- for an ambient temperature of 55 °C 1.5 A

for the mean current value with a load cycle of 10 s duration.

The temperature corner points may be interpolated linearly.

The short-term current rating of the control valve outputs is 3.0 A (200 ms).

In the event of an overload, the F1900 or F1901 fuse on the HLA control unit blow.

Fuse

The switched 24 V outputs for axes 1 and 2 are protected by F1900 (axis 1) or F1901 (axis 2) miniature fuses.

1) I = Input, O = Output

Max. terminal cross–section 2.5 mm².

Caution
The +24 V outputs for shut–off valves for axes 1 and 2 are short–circuit proof. The energy absorbed when inductive loads are disconnected must be limited to 1.7 J by the user. When the supply polarity is reversed, the outputs are not protected against overload.

Warning
If the polarity of the 26.5 V supply is reversed, then the shut–off valves will open immediately, even if the NC or closed–loop control is not in operation!
Notice
Each of the shut-off valves must be connected directly using two conductors connected to pins 2/3 of X431 or X432!

A current-compensated interference suppression coil is inserted at the input for the external incoming supply terminal P24, terminal M24 (pins 5 and 6 of X431).

Terminal M24 and terminal MV1/MV2 may therefore not be reversed or short-circuited.

The internal enable voltage (FRP/9) is provided in order to supply the BEROs, and terminals 663 may not be used to supply the hydraulics components. The hydraulic components must be supplied via incoming supply P24. The voltages may not be connected in parallel.

Input enable
Module-specific enabling commands are issued by terminal 663. As no power section is installed, no relay is available. The input is therefore evaluated via optocouplers in the HLA module and also acts on the shut-off valves. The enable voltage can be taken from terminal 9.

Terminal 663 is referenced to the internal enable voltage (ground, terminal 19).

4.4.3 Test sockets (diagnostics)

Measuring sockets
The start-up tool or an MMC102/103 can be used to assign internal signals to the test sockets on the 611D drive (in conjunction with SINUMERIK 840D), where the signals are then available as analog values.

![Diagram of test sockets]

Functionality
Three 8-bit digital/analog converter (DAC) channels are available on the 611D hydraulics module. An analog image of various drive signals can be connected through to a test socket via these converters.

Only a window of the 24-bit wide drive signals can be displayed with the 8 bits (=1 byte) of the DAC. For this reason, the shift factor must be set to determine how fine the quantization of the selected signal must be. The normalization factor is determined when parameterizing and displayed to the user.
4.5 "ANA module" control board

Description
Up to two analog axes can be controlled by using the ANA control unit. The ANA module results when the ANA control unit is inserted in the 50 mm wide universal empty housing.

The control unit can also be used as an HLA control unit for hydraulic axes. This double-axis board can be used in mixed operation (HLA/ANA).

An analog axis can be used very much like a digital axis. It can be programmed like a digital interpolating path axis or spindle. Pure functions of the SIMODRIVE 611 drive control system are, of course, not possible for external drive units linked via an analog speed setpoint interface. (These are functions which are dependent on feedback within the axis and communication by means of the drive bus, e.g. SINUMERIK Safety Integrated.) If necessary, separate EMC measures must be taken for external drive units.

Note
The ANA module is described in detail in:

References: /FBANA/, SINUMERIK 840D SIMODRIVE 611 digital ANA module, Description of Functions

Features
The ANA module has the following features:

- Software and data
  The communications interface is compatible with SIMODRIVE 611 SRM(FD)/ARM(MSD) for supported services. Code and data structure is analogous to SIMODRIVE 611 SRM(FD)/ARM(MSD).

- Hardware
  Integration into the SIMODRIVE 611 system is compatible with SIMODRIVE 611 digital SRM(FD)/ARM(MSD). Essentially, this involves the following interfaces:
  - Drive bus
  - Equipment bus
  - Power supply concept

- ANA control unit (2-axis)
  - \( n_{\text{set}} \) output ± 10 V
  - Connection for 2 sensors per axis
  - Control of an analog drive amplifier

- Terminals and diagnostics
  - BERO input per axis
  - Module-specific enable signal
  - Test sockets (diagnostics)
4.5.1 System overview

A complete 840D control with ANA module comprises various individual components. These are listed below.

- MCP
- MMC CPU
- Equipment bus
- Battery and fan slot
- ANA module
- NCU
- Digital I/O (high-speed NC I/O)
- Measurement (2x)
- Handwheel (2x) (1x of M)
- Measurement (2x)
- NCU box
- PCMCIA
- Line infeed
- Distributor box
- Battery and fan slot
- HHU
- NCU box
- Cable distributor
- ANA module
- Analog drive amplifier
- Analog sensors 0...10 V
- Enable
- Position sensing
- SITOP power (external power supply)
- External 26.5 V supply (this is only required when using terminals PV1/MV1 or PV2/MV2)
- Note: Shown for one analog axis

Fig. 4-10 System components
**ANA control unit**

![Diagram of ANA control unit](image)

Fig. 4-11 ANA control unit (2–axis)
4.5.2 Wiring

Line supply connection

SINUMERIK 840D and the ANA module are supplied from the SIMODRIVE line supply voltage or from the SIMODRIVE monitoring module via the equipment bus. There must be at least one NE module in the equipment group when an ANA module is used. No provision has been made for any other type of voltage supply and failure to use the supply provided could damage the unit.

Notice

It is not permissible to operate an ANA module on its own with a SIMODRIVE monitoring module!

Power is supplied to downstream electrical axes via the DC link busbars (40 mm²) of the carrier module.

Measuring systems

One position encoder for each axis can be evaluated on the ANA module.

- X101: Axis 1
- X102: Axis 2

The measuring system must always be plugged into the connector of the associated axis.

1) I = Input, O = Output

Notice
A connection (jumper) between X431.6 and X432.3 is not permissible!

Max. terminal cross-section 2.5 mm².
It is only necessary to supply terminals X431 pins 5 and 6 with 24 V if the 24 V outputs of connectors X111/112, X121/122 or X431/432 are to be used.
4.5.3 Bus interfaces

**Input enable**

The module-specific enable is realized using terminal 663. The input is evaluated via the optocoupler in the ANA module. The enable voltage can be taken from terminal 9.

Terminal 663 is referenced to the internal enable voltage (ground, terminal 19).

**Drive bus**

(refer to SIMODRIVE 611 digital)

- X141: Input
- X341: Output

A bus terminator must be plugged into the last module.

**Equipment bus**

Power Modules

5.1 Description

General
Together with the control module, the power module forms the drive module, for feed or main spindle applications.

Motors that can be connected
The power modules can be used to operate the following motors:

- 1FT6, 1FK6 and 1FK7 servo motors
- 1FW6 built-in torque motors (direct drives)
- 1FN linear motors
- 1PH main spindle motors
- Standard induction motors; if IM operation is selected, only inverter pulse frequencies of 4 kHz and 8 kHz are permissible.
- 1PM hollow shaft motors for main spindle drives (direct drives)
- 1FE1 main spindle motors
- 2SP1 motor spindle
- Third-party motors, if according to the motor manufacturer the motor meets the requirements for sine modulation, insulation, and dV/dt resistance (see Chapter 8.1).

For special motors with a low leakage inductance (where the controller settings are not adequate), it may be necessary to provide a series reactor in the form of a 3-arm iron core reactor (not a Corovac reactor) and/or increase the inverter pulse frequencies of the converter. Motors with a low leakage inductance are, from experience, motors that can achieve high stator frequencies (maximum motor stator frequency > 300 Hz) or motors with a high rated current (rated current > 85 A).

Available power modules
A wide range of 1-axis or 2-axis power modules is available. These modules are graded according to the current ratings and can be supplied with three different cooling techniques.

The current-related data refers to the series-preset values. At higher frequencies of the fundamental waves or for higher clock cycle frequencies, ambient temperatures and installation altitudes above 1000 m above sea level, power deratings apply as subsequently listed.

Wiring
Matched, pre-assembled cables are available to connect the motors. Ordering information is provided in the "Motors" section of the NC 60 catalog.

Shield terminal plates are available to meet EMC requirements when using shielded power cables.
The equipment bus cable is included in the scope of supply of the power module. The drive bus cables must be ordered separately for the digital system.

The current data of the power modules (PM modules) are normalized values to which all of the control units refer. The output currents can be limited by the control unit being used.

---

**Caution**

After the control unit has been inserted, the retaining screws of the control unit front panel must be tightened in order to establish a good electrical connection to the module housing.

---

The power module is equipped with overload protection, which when correspondingly dimensioned, prevents the motors and cables from being overloaded. The overload protection functions as described in the documentation SINUMERIK 840D/810D drive functions, Chapter 2.4.1. It does not fully comply with the requirements as specified in UL508C Version 2010, regarding cable protection.
5.2 Operating modes

Feed drives

- with synchronous motors (FD)
  - 1FT6, 1FK6 and 1FK7 servo motors
  - 1FW6 built-in torque motors (direct drives)
  - 1FN linear motors

Main spindle drives

- with induction motors (MSD–IM)
  - 1PH main spindle motors
  - 1PM hollowshaft motors for main spindle drives (direct drives)
  - standard induction motors (sensorless)
    If IM operation is selected, only inverter pulse frequencies of 4 kHz and 8 kHz are permissible.

- with synchronous motors (MSD–SRM)
  - 1FE1 main spindle motors
  - 2SP1 motor spindle

Note
For the MSD–SRM operating mode (high-speed MSD synchronous applications), inverter pulse frequencies are set that differ from the rated frequencies. This consequently ensures an optimum ratio between the inverter pulse frequency and the output frequency.

The derating resulting from this should be taken into account when selecting the power module.

The frequencies relevant when engineering the system should be appropriately taken from the following documentation.

Reference:
- PJFE/ Configuration Manual, 1FE1 Synchronous Built-in Motors
- BU/ Catalog NC 60 2004
- PMS/ Configuration Manual ECO Motor Spindles for 2SP1 Main Spindle Drives
- WEISS GmbH/Operating Instructions ECO Spindle Units Type 2SP1...
5.3 Technical data

General

The technical data of the power modules is specified in Table 5-1 for the 1–axis version and in Table 5-2 for the 2–axis version.

The specified values are valid for:

- The specified rated frequency (inverter pulse frequency)
- Maximum ambient temperature of 40 °C
- Installation altitude < 1000 m above sea level

Derating must be applied for conditions that deviate from those specified above. The power modules do not have any overload protection, but only a current acquisition without its own processing. The overload protection is realized in the SIMODRIVE 611 control unit.

Definition of the currents

Also refer to the definition of the load duty cycles (Fig. 5-2 to 5-5)

- FD mode
  - \( I_n \) Continuous nominal current, rated current
  - \( I_{\text{max}} \) Peak current
- Operating modes, MSD–IM and MSD–SRM
  - \( I_n \) Continuous nominal current, rated current
  - \( I_{S6–40\%} \) Current for maximum of 4 min. for the S6 load duty cycle
  - \( I_{\text{max}} \) Peak current
  - \( I_{\text{min}} \) Minimum motor current
  - \( n_{FS} \) Speed at the start of field weakening
  - \( I_{0\text{Mot}} \) Motor no–load current in \( A_{\text{rms}} \)

The following restrictive conditions must be met:

for induction motors:

- The no–load current of the motor (\( I_{0\text{Mot}} \)) must be less than the rated current of the power module (according to Table 5-1).
- On the basis of the actual current value resolution, the lowest occurring no–load current of the motor must satisfy the following condition:

\[
\frac{n_{FS}}{h_{\text{max}}} \cdot I_{\text{0Mot}} \geq I_{\text{min}} \quad (I_{\text{min}} \text{ according to Table 5-1})
\]

for synchronous motors:

A ratio of \( I_{\text{max, powersection}}/I_{0\text{_100K} \text{ (motor)}} \) — 5 should not be exceeded for synchronous motors.

Definition of the power ratings

Appropriate values are specified in Table 5-1 and 5-2 to dimension the cabinet cooling. These are defined as follows:

- \( P_{\text{Vtot}} \) Total power loss dissipated by the module
- \( P_{\text{Vext}} \) Power loss that can be dissipated externally or using hose cooling
- \( P_{\text{Vint}} \) Power loss that cannot be dissipated using hose cooling or external cooling (this power loss remains in the control cabinet)

For components with internal cooling, the complete dissipated power loss remains in the control cabinet.

1) For a module width of 300 mm with external cooling, mounting frames are required that must be separately ordered. The fan assembly required to mount the built-on fan is included in the scope of supply of the mounting frame. The built-on fan must be separately ordered! Mounting frames are also available for smaller module widths. However, these are not required if openings are cut out in the rear cabinet panel for the module heatsinks as shown in this Configuration Manual.

2) For 6SN1123–1AA0–01A0 and 6SN1124–1AA0–0FA0 and 6SN1162–0BA02–0AA2, the built-on fan 6SN1162–0BA02–0AA2 is required.

3) For a module width of 300 mm with external cooling, mounting frames are required that must be separately ordered. The fan assembly required to mount the built-on fan is included in the scope of supply of the mounting frame. The built-on fan must be separately ordered! Mounting frames are also available for smaller module widths. However, these are not required if openings are cut out in the rear cabinet panel for the module heatsinks as shown in this Configuration Manual.

4) True for induction motors and applies to the no-load current.

1) For IM operation, corresponding to the selected 4/8 kHz inverter pulse frequency, an appropriate derating must be observed.
2) True for induction motors and applies to the no-load current.
Load duty cycles

- Rated load duty cycles for FD operation

![Fig. 5-2 Peak current load duty cycle with preload condition](image1)

![Fig. 5-3 Peak current duty cycle without preloading condition](image2)

- Rated load duty cycles for MSD–IM and MSD–SRM

![Fig. 5-4 S6 load cycle with pre–load condition](image3)

![Fig. 5-5 S6 peak–current load cycle with pre–load condition](image4)
5.4 Current reduction/derating

The current has to be reduced if one or more of the following limitations/secondary conditions apply:

- Selected inverter pulse frequency \( f_T > f_0 \)
- Installation altitude > 1000 m above sea level
- Ambient temperature \( T_U > 40^\circ C \)

Notice

The currents must be reduced for \( I_n, I_{S6} \) and \( I_{max} \) in the same way.

All of the relevant limitations/secondary conditions must be taken into account with an appropriate reduction factor (refer to the calculation example, Chapter 5.4.4).

5.4.1 Pulse frequency power modules

The current should be reduced from the reference frequency \( f_0 \) onwards according to the following rule:

\[
X_T = 100\% - \frac{(100\% - X_L) \cdot (f - f_0)}{8\, \text{kHz} - f_0}
\]

Definitions

The pulse frequency of the power modules (inverter) must be at least factor 5 for the maximum motor frequency!

- \( f_0 \) Pulse frequency reference frequency in accordance with the technical data
- \( f \) set inverter pulse frequency
- \( T_U \) ambient temperature
- \( X_L \) power module-specific derating factor for the inverter pulse frequency
- \( X_T \) derating factor for the inverter pulse frequency
- \( X_H \) derating factor for the ambient temperature
- \( X_{TU} \) derating factor for the installation altitude as a %

Calculation example

See Chapter 5.4.4
5.4 Current reduction/derating

Pulse frequency–dependent derating

Factor XT, diagram only for illustration, calculation example in Chapter 5.4.4.

- for MSD–IM and MSD–SRM or IM operation (sensorless)

![Diagram](image)

Fig. 5-6  Power as a function of the inverter pulse frequency for MSD–IM and MSD–SRM

- for FD

![Diagram](image)

Fig. 5-7  Power as a function of the inverter pulse frequency for FD
5.4.2 Temperature–dependent derating

For an ambient temperature \( T > 40 \, ^\circ\text{C} \), derating is required according to the following rule:

\[
X_{TU} = 100\% - 2.5\% (T_U - 40 \, ^\circ\text{C})
\]

**Notice**

The maximum ambient temperature for operation of \( T_U = 55 \, ^\circ\text{C} \) may not be exceeded.

5.4.3 Installation height–dependent derating

For an installation altitude \( h > 1000 \, \text{m} \) above sea level, derating is required according to the following derating characteristic:
5.4.4 Calculation examples

Temperature/installation altitude derating

- Supplementary conditions
  
  Power module: 6SN1123–1AA0:–0EA1
  Operating mode: FD
  Inverter pulse frequency: 6.3 kHz
  Installation altitude: 2000 m above sea level
  Ambient temperature: 45 °C
  \[ X_L = 55\% \]
  \[ f_0 = 4.0 \text{ kHz} \]
  \[ I_N = 56 \text{ A} \]
  \[ I_{\text{max}} = 112 \text{ A} \]

- Determining the derating factors
  
  \[ X_T = 100\% - \frac{(100\% - 55\%) \times (6.3 \text{ kHz} - 4.0 \text{ kHz})}{8.0 \text{ kHz} - 4.0 \text{ kHz}} = 74.125 \% \]
  \[ X_{\text{TU}} = 100\% - 2.5\% \times (45 \degree \text{C} - 40 \degree \text{C}) = 87.5\% \]
  \[ X_H = 85\% \]

- Calculating the permissible current values
  
  \[ I_{\text{Nred}} = I_N \times X_T \times X_{\text{TU}} \times X_H = 56 \text{ A} \times 0.74125 \times 0.875 \times 0.85 = 30.8 \text{ A} \]
  \[ I_{\text{maxred}} = I_{\text{max}} \times X_T \times X_{\text{TU}} \times X_H = 112 \text{ A} \times 0.74125 \times 0.875 \times 0.85 = 61.7 \text{ A} \]

Current reduction

- Supplementary conditions
  
  Power module: 6SN1123–1AA0:–0EA1
  Operating mode: FD
  Inverter pulse frequency: 6.3 kHz
  Installation altitude: <1000 m above sea level
  Ambient temperature: <40 °C
  \[ X_L = 55\% \]
  \[ f_0 = 4.0 \text{ kHz} \]
  \[ I_N = 56 \text{ A} \]
  \[ I_{\text{max}} = 112 \text{ A} \]

- Determining the derating factors
  
  \[ X_T = 100\% - \frac{(100\% - 55\%) \times (6.3 \text{ kHz} - 4.0 \text{ kHz})}{8.0 \text{ kHz} - 4.0 \text{ kHz}} = 74.125 \% \]
  \[ X_{\text{N6.3}} = I_N \times X_T \times X_{\text{TU}} = 56 \text{ A} \times 0.74125 = 41.5 \text{ A} \]

- Calculating the permissible current values
  
  \[ I_{\text{N6.3}} = I_N \times X_T \times X_{\text{TU}} \times X_H = 56 \text{ A} \times 0.74125 \times 0.875 \times 0.85 = 41.5 \text{ A} \]

\[ I_{\text{max6.3}} = I_{\text{max}} \times X_T \times X_{\text{TU}} \times X_H = 112 \text{ A} \times 0.74125 \times 0.875 \times 0.85 = 83.0 \text{ A} \]
5.4 Current reduction/derating

Derating example

- Installation altitude: e.g. Puebla, Mexico, 2200 m above sea level
  Derating to 83% \( I_N \) necessary!

- Temperature: e.g. internal temperature of the switchgear cabinet with 45 °C, no air–conditioner
  Derating to 87% \( I_N \) necessary!

- Power module clock cycle frequency 6SN1123–1AA0–0EA2
  \( X_L = 50\% \): e.g. for a 6.3 kHz spindle application
  Derating to 68% \( I_N \) necessary!

Result:

Derating for the power unit to:
\( 83\% \times 87\% \times 68\% = 50\% \) \( I_N \) required!

Derating for the line supply infeed to:
\( 83\% \times 87\% = 72\% \) \( I_N \) required!
### 5.4 Current reduction/derating

5.5 Operating power modules from an unregulated infeed

The drive modules can be operated from both unregulated and regulated supply modules belonging to the SIMODRIVE 611 drive converter system. The engineering and power data of this Configuration Manual refer to operation with the regulated infeed/regenerative feedback modules. This data should be corrected, if required, when operated from unregulated infeed modules.

Operating drive modules with PH and 1FE1 motors and induction motors from an unregulated infeed

When operation is with an unregulated infeed (e.g. UI module or unregulated operated I/R module), a lower maximum motor output is available in the upper speed range than with the use of the infeed/regenerative feedback module.

As a result of the low DC link voltage of 490 V (for a line supply infeed with 400 V 3–ph. – 10%) for the UI module or unregulated operated I/R module, the available continuous output is given by:

If

\[
\frac{U_{ZK}}{1.5 \times V_{N \text{ motor}}} < 1
\]

then, only the following continuous power is available

\[
P_{\text{continuous}} = P_N \times \frac{U_{ZK}}{1.5 \times V_{N \text{ motor}}}
\]

\(U_{\text{DC link}} = \) line voltage \(\times 1.35\)

- For 360 V –10 % line voltage
  \(U_{\text{DC link}} = 436 \text{ V}\)
- For 400 V –10 % line voltage
  \(U_{\text{DC link}} = 486 \text{ V}\)

\(V_{N \text{ motor}}\) should, for the particular motor, be taken from the appropriate documentation (refer to Appendix, References).

As a result of the lower DC link voltage, it is possible that motor rated speeds will no longer be able to be reached, refer to Engineering the motors. In this case, the speed of the motors, and therefore the power, must be appropriately reduced.

![Speed/power graph](image-url)
5.5 Operating power modules from an unregulated infeed

**Reader’s note**
Selecting the power rating for UI modules, refer to Chapter 6.7.4.

For the 28 kW UI, the pulsed resistors must be separately ordered and externally mounted.

For higher regenerative feedback powers, a separate braking resistor module must be provided or the regenerative power reduced by using longer braking times.

**Operating drive modules with 1FT6, 1FK and 1FN motors on uncontrolled infeeds**

As a result of the lower DC link voltage of 490 V\(^1\) for the UI module (600 V for the I/R module), under certain circumstances, the following restrictions must be expected:

- Reduction of the dynamic drive properties in the upper speed/velocity range
- Lower utilization of the rated motor speed/velocity if the requirement relating to overload is kept

---

1) For a line supply infeed with 3–ph. 400 V AC –10%.

#### Key
- Terminal area for flexible cable with end sleeves (with or without plastic collars)
- Terminal area for flexible cables with terminal pin
- IP20 is guaranteed when correctly used, e.g. insulated pin-type cable lugs

1) Size of the screw for the protective conductor connection
2) Tightening torque of the terminals or connectors

---

**Warning**

The internal overload monitoring function of the power modules only protects the cable if it is dimensioned/selected corresponding to the power module currents. If smaller cross-sections are selected, then the user must ensure the appropriate level of cable protection, e.g. by suitably setting the control parameters.

---

**Note**

For UL certification, only use copper cables that have been appropriately dimensioned/selected for the operating temperature $\geq 60\,^\circ\mathrm{C}$. 
5  Power Modules

Infeed Modules

6.1 Description

General information

The infeed modules are used to connect the drive group to the line supply. The infeed/regenerative feedback module (I/R module) and the module for the unregulated infeed (UI module) are used to input power into the DC link. Furthermore, the I/R, UI, and the monitoring module also provide the electronics power supply for the connected modules.

The infeed modules do not have any comprehensive overload protection. Such overload protection must be provided by the configuration and correct setting of the current values in the control boards.

UI module

For the UI module, when the motor brakes, the drive energy injected into the DC link is converted into heat in the braking resistors and dissipated to the environment. These braking resistors are either integrated or mounted. When required, one or more additional pulsed resistor modules (PR modules) can be used within the limits specified when engineering the system.

This module is used for the following applications:

- Machines with few or short braking cycles, low braking energy
- Drive groups with limited dynamic demands, in particular for the main spindle drive

I/R module with HFD reactor

I/R modules and HF/HFD commutating reactors form the step–up converter (7 kHz) for controlling the DC link voltage and enabling a regenerative feedback. This module is used for the following applications:

- Machines with high dynamic requirements placed on the drives
- Frequent braking cycles and high braking energy
- Control cabinet designs optimized for low operating costs

Note

The HFD line reactor is required in order that the I/R module can function, as this is cyclically short–circuited for the step–up controller, voltage control function to be active!

Overvoltage limiting module

The overvoltage limiting module limits sporadic, transient overvoltages, for example that can occur as a result of switching operations in the line supply.
6 Infeed Modules

6.1 Description

Monitoring module

The monitoring module contains a complete electronics power supply for the equipment bus and the central monitoring functions for a separate drive group. The power is normally supplied from the 3–ph. 400 to 480 V AC line supply. For emergency retraction in case of a power failure, the power supply can also be connected to the DC link in parallel (see Section 8.15).

The monitoring module is required if a higher number of drive modules in a group exceeds the electronics power supply of the infeed module (I/R or UI module). The monitoring module also allows groups of drive modules to be created in multiple cabinet compartments or tiers.

Arrangement

The I/R, UI and monitoring module are located as the first module at the left in the drive group.

The mounting surface for the line supply infeed and drive modules as well as the commutating reactors and line filter must be mounted to the mounting panels through a low–resistance connection (e.g. galvanized plates and panels).

Line filters, line filter modules and shielded cables are available in order to comply with the CE requirements regarding the radio interference voltage limit values. Shield terminal plates are available to meet EMC requirements when using shielded power cables.

Operating conditions

</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Σ DC link capacitance of the drive group [µF]</td>
</tr>
</tbody>
</table>

Fig. 6-1 DC link pre–charging frequency

Note

In the “standby mode” of the line supply infeed, pulse inhibit for the power modules, terminal 63 should also be used to inhibit the pulses in the infeed. The DC link remains at the non–regulated level; this means that when the pulses are enabled, it is immediately regulated and is ready to operate.

The cycle indicated above also applies to the starting frequency of the power supply (from the line supply or X181).

The maximum starting frequency for the power supply is five times within a five minute period.

Notice

Failure to comply with this boundary condition triggers a thermal protection in the device, preventing further startup of the power supply.

Consequence: All LEDs remain dark.

Remedy: Switch off the power and wait at least two minutes before switching on the power again. For a 6–conductor connection, it is sufficient to interrupt the power supply for two minutes at connector X181.

6.2 Interface overview

Danger

Protection from direct contact by means of SELV/PELV is permitted only in areas with equipotential bonding and in dry interior spaces. If these conditions are not given, other protective measures against electric shock must be taken, e.g. protection through protective impedances or limited voltage or by implementing protection class I and II.

Only PELV or SELV voltages may be connected at terminals with either PELV or SELV voltages (refer to EN 60204–1, Section 6.4).

For Order Nos. for coding connectors, refer to Catalog NC60.

Refer to the information in the following tables.
### 6.2.1 Interface overview, NE modules

The interface description applies to all NE modules except for the 5 kW UI module. The interface of the 5 kW UI module has a separate description (see Section 6.2.2).

</tbody>
</table>

1) I = input; O = output; NC = NC contact; NO = NO contact; (for signal, NO = high; NC = low)

2) Term. 19 is the reference ground (connected through 10 kΩ to general reference ground X131/T.15 inside the module)

3) Terminal 15 must not be connected to PE, to terminal 19 or to external voltage sources.

4) The terminal may be used only for enabling the associated drive group.

5) The first data applies with pin–type cable lug. The second data is used for finely–stranded cable without end sleeve.

6) The grounding clip is used to ground the DC link M600 busbar through 100 kΩ (must be closed and must not be closed if RCCBs are used, see also Chapter 8.1; the grounding clip must be opened if the system is subject to a high–voltage test).

7) RESET = resets the fault memory, edge–triggered for the complete drive group (terminal “R” → Terminal 15 = RESET)

8) Terminals 111–213, positively–driven opening contacts (for I/R 16 kW and UI 10 kW, only from Order No. [MLFB]:

9) For UR 16 kW (from version E) and UI 10 kW (from version F) the following apply:

10) Terminals 111–113 NO contact not positively–driven

11) Terminals 111–213, positively–driven opening contacts (series circuit of NC contact, main contactor and NC contact, pre–charging contactor)

12) Terminals 111–113, positively–driven NO contacts

13) Terminals 111–13, positively–driven NO contacts

15) For UI certification, only use copper cables dimensioned for an operating temperature \( \leq 60^\circ \text{C} \)

16) Max. permissible connected power: \( P_{max} \leq 43 \text{ kW}; \) max. permissible current load: \( I_{max} \leq 72 \text{ A} \)

17) Warning

In order to avoid damage to the infeed circuit of the NE modules, when controlling/energizing terminal 50 at X221 (PR module, DC link fast discharge) it should be ensured that terminal 48 of the NE module is de–energized (the module is then electrically isolated from the line supply). The feedback signal contacts from the main contactor of the NE module (X161 term. 111, term. 113, term. 213) must be evaluated.

**Key**
- Terminal area for flexible cable with end sleeves (with or without plastic collars)
- Terminal area for flexible cables with terminal pin
- IP20 is guaranteed when correctly used, e.g. insulated pin-type cable lugs

1) Size of the screw for the protective conductor connection
2) Tightening torque of the terminals or connectors
6.2.4 Three–conductor connection (standard circuit)

Only PELV/SELV circuits may be connected at terminal 19 (FR–).

Other terminal 19

Pushbutton contact

Other terminal 48

Reactor, only for I/R module and UI 28 kW

Line filter

Line fuses for I/R or UI module, refer to Chapter 7.3.1

Main switches

Supply system

Notice
1) Jumpers in the condition when supplied. Depending on the application, remove the jumpers (ref. to the circuit examples in Section 8.7).
2) For I/R modules with setting for regulated operation the following applies (refer to switch S1, Chapter 6).
   Term. 48 must be de–energized \( \geq 10 \) ms earlier before the line contacts of the main switch open (e.g. using a leading contact).
3) Terminals L1 and L2 are only available for I/R modules 80 kW and 120 kW.
4) Grounding bar for line supplies with poor chassis connection to ground, open when the equipment is supplied.
5) Or external contactor infeed (connection)
6) Or external contactor infeed (connection not permitted).

Fig. 6-6 Three–conductor connection (standard circuit)
6.2 Interface overview

6.2.5 Description of the interfaces and functions

Switch S1

Switch S1 to set various functions is provided on the upper side of the NE and monitoring module or on the front side/panel for the UI module 5 kW; refer to Chapter 6.3.

Terminal 19

**EN–**

Reference potential for the enable voltage terminal 9, non-floating (with electrical isolation) (connected to the general reference ground terminal 15 through 10 kΩ). Terminal 19 is not permitted to be connected to terminal 15. (Connect to the PE bus or X131.)

When controlling the enable signals using electronic outputs that switch to high (PLC), terminal 19 must be connected to the 0 V reference potential (ground) of the external power supply.

The circuits/power source must satisfy the requirements for PELV (Protection Extra–Low Voltage) and SELV (Safe Extra–Low Voltage) functional extra–low voltage with safe separation in accordance with EN 60204–1; 6.4.

**EN+**

Only use the +24 V enable voltage for the internal enable signals of the NE and drive modules.

Maximum power supply load: 500 mA
(corresponds to 8 EP; 1 optocoupler input requires 12 mA, for UI 5 kW ––> 1 A)

Terminal 9

**EN+**

Only use the +24 V enable voltage for the internal enable signals of the NE and drive modules.

Maximum power supply load: 500 mA
(corresponds to 8 EP; 1 optocoupler input requires 12 mA, for UI 5 kW ––> 1 A)

Terminal 48

**Start**

This terminal has the highest priority. A defined power–on and power–off sequence of the NE module is initiated using terminal 48.

If terminal 48 is enabled (energized), then internally, the pre–charging sequence is initiated.

( interrogation VDC link ≥ 300 V and VDC link = \sqrt{2} \times U_{line \ supply} − 50 V).

After the DC link has been charged, then, simultaneously

• after 500 ms ––> the pre–charging contactor is opened and the main contactor is closed.

• after 1 second ––> the internal enable signals are then issued.

If terminal 48 is de–energized, then initially, after approx. 1 ms, the internal pulse enable signals are inhibited and then the DC link is electrically isolated from the line supply delayed by the drop–out time of the internal line contactor.

If terminal 48 is opened (enabled) during the load operation, the load operation is first completed. The inhibit functionality for terminal 48 does not takes effect until the load operation is complete, provided terminals NS1–NS2 are jumpered.

Terminals NS1, NS2

 Coil circuit of the internal line and pre–charging contactor

If the line contactor is opened (de–energized) by interrupting the coil circuit using electrically isolated (floating) contacts, then the DC link is safely and electrically disconnected from the line supply (signal contact, terminals 111–213 must be interrogated).

The terminals have a safety–relevant function. The shutdown using terminals NS1–NS2 must be realized at the same time as or delayed with respect to terminal 48 start (refer to Section 8.7 Circuit examples = 2 and = 4).

Max. cable length 50 m (2–conductor cable) for 1.5 mm² cross–section

Terminal 63

**Pulse enable**

For the pulse enable and inhibit functionality, this terminal has the highest priority. The enable and inhibit functions are effective after approx. 1 ms simultaneously for all of the modules including the NE module. When the signal is withdrawn, the drives “coast down” unbraked.
Standby operation of the infeed:

If an infeed module is to be kept in the ready state for a longer period of time (DC link charged), then in order to avoid unnecessary switching losses and reactor losses, a pulse inhibit should be enabled! The DC link voltage then remains at the non-regulated value and is again ready in the regulated mode immediately after the pulses have been enabled.

**Terminal 64**

**Drive Enable**

The drive modules are enabled using terminal 64. The modules are simultaneously enabled or inhibited after approx. 1 ms.

If terminal 64 is inhibited, then $n_{\text{set}} = 0$ is set for all drives and the axes brake as follows:

- For 611D/611 universal/ANA/HLA drives, the pulses are cancelled after a selectable speed has been undershot or after a selectable timer stage has expired. The axes brake along the selected limits (MD 1230, 1235, 1238). For spindles, a ramp can only be achieved using regenerative limiting (MD 1237).
6 Infeed Modules

6.2 Interface overview

**External switching voltage for the coil circuit of the line contactor**

Is used to supply the coil circuit of the internal line contactor only at the 80 kW and 120 kW I/R modules (do not connect between the I/R module and reactor).

Fuse: $I_r \geq 4$ A, version gL
2–ph. 360 to 457 V AC/45 to 53 Hz; 400 to 510 V/57 to 65 Hz

**Terminals L1, L2**

Matching transformer for the coil connections L1, L2 at the line supply voltage 230 V and 380 V; for two 5TK5022–0AR0 contactors.

1) Order No.
mdexx GmbH
Richard-Dunkel-Straße 120
28199 Bremen
GERMANY
Phone: +49 421 5125-0
E-Mail: info@mdexx.de

**Note**

If, for the 80/104 kW or 120/156 kW I/R module, the line supply voltage at terminals L1, L2 fails or fuses F1, F2 trip, then only the pulses in the I/R module are cancelled and the internal line contactor drops–out.

This is displayed using the "line fault" LED, the ready relay and also the contactor signaling contacts. In this case, in order to re–close the internal line contactor, terminal 48 must be inhibited (de–energized) and re–energized after ≥ one second or the unit must be powered–down/powered–up.
### Terminal R

**Reset**

The fault signal is reset using a pushbutton (pulse edge) between terminal R and terminal 15.

For the SIMODRIVE 611 universal HRS / HRS2 control unit, the reset is effective if, in addition, terminal 65 "controller enable" is also inhibited.

### Terminal 112

**Set-up operation deaktivieren**

Für den Normalbetrieb ist die Terminal 112 jumpered by default with terminal 9 (+24 V enable voltage). Bei offener Klemme 112 ist der Einrichtbetrieb aktiv.

Open: The step–up converter voltage control is set to start inhibit, monitoring disabled, die Einspeisung erfolgt ungeregelt.

Terminal 112 can only be used for SIMODRIVE 611 analog and not for SIMODRIVE 611 digital/universal.

### Terminals AS1, AS2

**Signaling contact, start inhibit DC link controller Einrichtbetrieb (Anlaufsperr Hocchsetzsteller)**

Terminals AS1 – AS2 closed means that "start inhibit is effective" "Anlaufsperr für Hochsetzsteller ist wirksam" (i.e. terminal 112 = open, setup mode)

(not available for UI modules 5 kW, 10 kW, 28 kW)

### Terminal X131

**Reference potential, electronics**

If analog setpoints are routed from an external controller to the drive group, then wire an equipotential bonding conductor via terminal X131. This cable must be routed in parallel to the speed setpoint cable.

Cross–section = 10 mm²

### Terminals 7, 45, 44, 10, 15 (X141)

**Electronics power supply**

- Terminal 7: P24 +20.4 to 28.8 V/50 mA
- Terminal 45: P15 +15 V/10 mA
- Terminal 44: N15 –15 V/10 mA
- Terminal 10: N24 –20.4 to 28.8 V/50 mA
- Terminal 15: M 0 V (only for circuits of terminals 7, 45, 44 and terminal 10; max. load, 120 mA)

- Terminal 15 may not be connected to PE (ground loop)
- Terminal 15 may not be connected to terminal 19 (otherwise there will be a short–circuit through the reactor; terminal 15 is internally connected to X131).

### Terminals 2U1, 2V1, 2W1

Connecting terminals to separately supply the internal electronics power supply, e.g. through fused terminals (refer to the circuit example in Section 8.3.1).
In this case, jumpers 1U1–2U1, 1V1–2V1, 1W1–2W1 must be removed.

---

**Notice**

Observe additional information and instructions under Section 8.3 Monitoring module, and Section 8.15 Six-conductor connection!
Terminal P500, M500

Connect P500 and M500 for the internal coupling of the power supply to the DC link, e.g. for power failure concepts.

Notice
With this operating mode, terminals 2U1, 2V1, 2W1 of the power supply must be supplied with the line supply voltage between the I/R module and line reactor. The jumpers at connector X181 must under all circumstances be kept!

For a six–conductor connection (refer to Section 8.15), ensure a connection X181 (P500/M500) to the the DC link P600/M600 as specified in Section 8.15.2!

Terminals 111, 113, 213

Signaling contacts, internal line contactor

<table>
<thead>
<tr>
<th>Terminals</th>
<th>Contact Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>111–113</td>
<td>NO contact</td>
</tr>
<tr>
<td>111–213</td>
<td>NC contact</td>
</tr>
</tbody>
</table>

Terminals 72, 73.1, 73.2, 74 (X111)

Ready relay

Terminals 72 – 73.1: NO contact – closed for "Ready"
Terminals 73.2 – 74: NC contact – open for "Ready"

In addition to the interface signals provided, the terminal signal 72/73 also includes the line supply infeed monitoring as well as signals from the watchdog and the reset controller of the closed–loop control. This signal is available to the control unit independently of the processor.

The function of terminals 72/73 is not a safety function in the sense of the Machinery Directive 98/37/EU.

For the switch position S1.2 = ON "Fault signal" the relay pulls–in if the following conditions are fulfilled:
- Internal main contactor CLOSED (terminals NS1 – NS2 connected, terminal 48 enabled).
- No faults may be present (on any of the SIMODRIVE drives in the group).
- The NCU/CCU must have booted (SINUMERIK 840D, 810D).

For the switch position S1.2 = OFF "Ready" the relay is activated if the following conditions are fulfilled:
- Terminal 48 is enabled.
- Terminals 63, 64 = on.
- VSA with High Standard/High Performance or resolver for the ready setting, must be enabled (terminal 663, 65)

If there is a fault, the relay drops–out.

With the exception of the line monitoring function, all of the internal monitoring functions on all of the drive modules are effective at the relevant equipment bus and also the ready signal. For line supply faults, only the I/R module pulses are inhibited.

Notice
The ready signal must be evaluated in the external NC control in order to derive enable signals, inhibit signals, fault responses, etc.
6  Infeed Modules

6.2  Interface overview

Terminals 5.1, 5.2, 5.3 (X121)

**I²t pre–warning and motor temperature monitoring**

Terminals 5.1 – 5.2: NO contact open for "no fault"
Terminals 5.1 – 5.3: NC contact closed for "no fault"

**Notice**

No I²t monitoring of the infeed!

You must ensure sufficient power of the infeed module by setting this parameter accordingly in the configuration.

Terminals 5. □ must be externally evaluated for the machine responses, for example, in the PLC. When the motor temperature monitoring responds, the user/machine manufacturer must define what the response should/must be:

- Reduce the load on the machine
- Reduce the power
- Stop
- Shutdown

If the terminal is not evaluated, and the response that makes sense for this particular case is initiated in the machine control system, then this can destroy the system, converter or motor!

The relay is activated if:

- At NE module
  - Heatsink–temperature monitoring trips
- At 611D
  - Motor–temperature monitoring trips
  - Heatsink–temperature monitoring trips
  - I²t axis limiting responds
- At 611 universal HRS / HRS2
  - Motor–temperature monitoring trips
  - Heatsink–temperature monitoring trips
  - I²t axis limiting responds

**Input current, enable circuits:**

Terminals 48, 63, 64, and 65: Input current, optocoupler approx. 12 mA at +24 V
Terminal 663: Input current, optocoupler and start inhibit relay approx. 30 mA at +24 V

When selecting the switching devices and the auxiliary contact on the main switch, the contact reliability when switching low currents must be carefully taken into consideration.

**Switching capacity of the signaling contacts:**

The max. switching power of the signaling contacts is specified in the interface overviews of the modules in Chapters 4 and 6, and must be absolutely complied with!
Note

All of the connected actuators, contactor coils, solenoid valves, holding brakes, etc. must be provided with overvoltage limiting elements, diodes, varistors, etc. This is also true for switchgear/inductances controlled by a PLC output.

Display elements (LEDs)

The NE and monitoring modules have the following display elements (LEDs):

<table>
<thead>
<tr>
<th>LED</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>LED red – electronics power supply ±15 V faulted</td>
</tr>
<tr>
<td>2</td>
<td>LED red – 5 V voltage level faulted</td>
</tr>
<tr>
<td>3</td>
<td>LED green – external enable signals not present (terminal 63 and/or terminal 64 missing)</td>
</tr>
<tr>
<td>4</td>
<td>LED yellow – DC link charged (normal operation)</td>
</tr>
<tr>
<td>5</td>
<td>LED red – line supply fault (single or multi-phase power failure at terminals U1, V1, W1) ¹</td>
</tr>
<tr>
<td></td>
<td>– commutating reactor not available, incorrectly installed or incorrectly selected</td>
</tr>
<tr>
<td></td>
<td>– system fault level of the line supply or transformer too low</td>
</tr>
<tr>
<td>6</td>
<td>LED red – DC link overvoltage possible causes: Regenerative feedback off, setting-up operation, line fault, for UI, PW either not operational or too small, line supply voltage too high, dynamic overload, line filter inserted between I/R and the commutating reactor</td>
</tr>
</tbody>
</table>

Note:

¹) Detection time for line-supply failure, approx. 30 ms

Line-supply failure is detected from a 3-phase voltage < 280 V.

For a 1-phase line-supply failure, a pulse cancellation is initiated for the drive axes after approx. 1 min. (stored signal). This is valid for order number 6SN1114--000--0001

Fig. 6-7 Display element, NE and monitoring module

Effects of the display states:

1. LED red bright: Pulses are cancelled for the complete drive group
2. LED red bright: Pulses are cancelled for the complete drive group
3. LED yellow dark: Pulses are cancelled for the complete drive group
4. LED red bright: Pulses are only cancelled for the I/R module (regenerative feedback into the line supply no longer possible. Axes initially continue to run. Ready relay drops out)
5. LED red bright: Pulses are cancelled for the complete drive group
6. LED red bright: Pulses are cancelled for the complete drive group
Display, line fault

If a line fault is displayed or if the yellow LED does not light, the overvoltage limiter module must be checked.

Procedure:
1. Switch the unit into a no–voltage condition
2. Withdraw the overvoltage limiter module and insert connector X181 on the NE module.
   
   Does the NE module function correctly?
   
   Yes —–> The overvoltage limiter module is defective and must be replaced.
   
   No —–> Check the line supply and possibly the NE module/group.

Note

Operation can continue, but without overvoltage protection when the overvoltage limiter module is withdrawn and connector X181 has been removed from the NE module!

Operation without overvoltage limiter module is not in conformance with UL!

3. Insert a new overvoltage limiter module up to its endstop and reinsert connector X181 on the overvoltage limiter module.
### 6.3 Function overview and settings

#### General information

A switch S1 is provided on the upper side of the NE and monitoring module that is used to set the following functions (for UI 5 kW on the front side):

<table>
<thead>
<tr>
<th>Setting</th>
<th>ON</th>
<th>OFF</th>
</tr>
</thead>
<tbody>
<tr>
<td>V_{line} = 415 V ± 10% V_{DC link} = 625 V (^{(1)})</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Error message</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Regenerative feedback into the line supply off</td>
<td></td>
<td></td>
</tr>
<tr>
<td>V_{line} = 480 V (^{\ast}6% - 10%) (^{(2)})</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Controlled infeed off</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Sinusoidal current operation ((\text{on the line side}))</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Standard setting (\text{on the line side})</td>
<td></td>
<td></td>
</tr>
<tr>
<td>S1.1</td>
<td>ON</td>
<td>ON</td>
</tr>
<tr>
<td>S1.4</td>
<td>4</td>
<td>4</td>
</tr>
</tbody>
</table>

1) Only possible for I/R modules – for all NE modules, the monitoring thresholds are increased (± 2.5%).
2) For S1.4 = ON, S1.1, S1.3 and S1.6 have no effect.

![Fig. 6-8 DIL switch S1](image)

#### Note

For a configuration 480 V S1.4 = ON, only controlled regenerative feedback is realized, independent of the position of S1.5.

#### Notice

For I/R modules, sinusoidal current mode is the initial setting.

For operation with filters that are not listed in Table 6-6, the mode must be changed to squarewave current mode in order to protect the filter from thermal overload.

Before powering up or down using the main switch or a line contactor, terminal 63 (pulse enable) and/or terminal 48 (start terminal, contactor control) must be de-energized!

#### Switch S1.1

<table>
<thead>
<tr>
<th>Setting</th>
<th>OFF: I/R module U_{line} = 400 V ± 10%; V_{DC link} = 600 V ± 2.5%</th>
<th>ON: I/R module V_{line} = 415 V ± 10%; V_{DC link} = 625 V ± 2.5%</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>UI module V_{line} = 400 V ± 10%; V_{DC link} = V_{line} (\ast) 1.35</td>
<td>UI module V_{line} = 415 V (440 V) ± 10%; V_{DC link} = V_{line} (\ast) 1.35</td>
</tr>
<tr>
<td>Monitoring thresholds: (I/R, UI, monitoring modules)</td>
<td>PR on = 644 V; PR off = 618 V ± 2.5%</td>
<td>PR on = 670 V ± 2.5%; PR off = 640 V ± 2.5%</td>
</tr>
<tr>
<td></td>
<td>V_{DC link} = 695 V ± 2.5%</td>
<td>V_{DC link} = 710 V ± 2.5%</td>
</tr>
</tbody>
</table>

PR = Pulsed resistor
Switch S1.2
OFF: Ready signal (X111 ready relay)
For S1.2 = OFF, the relay pulls-in if the following conditions are fulfilled:
– Internal main contactor CLOSED (terminals NS1 – NS2 connected, terminal 48 enabled)
– Terminals 63, 64 = ON
– No fault present (also not at the FD 611 A Standard, 611 U, resolver and 611 D drives and HLA modules).
– FD with High Standard or resolver for the setting "ready" is enabled (terminals 663, 65)
– For 840D/810D, the NCU must have run-up

ON: Fault signal (X111 ready relay)
For S1.2 = ON, the relay picks up if the following conditions are fulfilled:
– Internal main contactor CLOSED (terminals NS1 – NS2 connected, terminal 48 enabled)
– No fault present (also not at the FD 611 A Standard, 611 U, resolver and 611 D drives and HLA modules).
– FD with High Standard or resolver for the setting "ready" is enabled (terminals 663, 65)
– For 840D and 810D the NCU must have run-up

Switch S1.3
OFF: Standard setting, regenerative feedback into the line supply active
I/R modules: 16 kW to 120 kW are capable of regenerative feedback.
UI module: 5 kW, 10 kW, 28 kW: The pulsed resistor in the module is effective and active.

ON: Regenerative feedback to the line supply is switched off
I/R modules: 16 kW to 120 kW: Regenerative feedback mode is disabled
UI module: 5 kW, 10 kW: The pulsed resistor in the module is not active
Valid for
UI 5 kW, Order No.: 6SN1146–1AB00–0BA1 and
UI 10 kW, Order No.: 6SN1145–1AA01–0AA1
Not valid for UI 28 kW. In this case, the external pulsed resistor must be disconnected.

Switch S1.4
OFF: Standard setting for all NE modules, refer to S 1.1
ON: \[ V_{\text{line}} = 480 \text{ V } \pm 6\% / -10\%; V_{\text{DC link}} = V_{\text{line}} \times 1.35 \text{ in infeed mode} \]
\[ V_{\text{DC link}} = 700 \text{ to } 750 \text{ V } \pm 2.5\% \text{ in regenerative feedback mode} \]
Monitoring thresholds: (I/R, UI, monitoring modules)
PR on = 744 V \pm 2.5\%; PR off = 718 V \pm 2.5\%
\[ V_{\text{DC link}} \geq 795 \text{ V } \pm 2.5\% \]
S1.4 exceeds the setting of S1.1

Please note! Unregulated operation in the infeed direction.

Warning
An incorrect switch setting ("OFF") for S1.4 when connected to \( U_{\text{line}} = 480 \text{ V} \) will overload the NE module and destroy it!
6 Infeed Modules

6.3 Function overview and settings

Switch S1.5

This function is only applicable in conjunction with I/R modules
Order No.: 6SN1145–1B00–0CA1
OFF: regulated infeed active (default setting)
ON: Unregulated operation in the infeed direction V<sub>DC link</sub> = V<sub>line</sub> • 1.35

Notice:
For unregulated operation of the I/R units with V<sub>line</sub> = 400 V/415 V, the power must be reduced (derated) as specified in Section 5.5.

Switch S1.6

OFF: Squarewave current operation (current with a squarewave shape is drawn from the line supply)
ON: This function is only applicable in conjunction with I/R modules with Order No.: 6SN1145–1B00–0CA1
sinusoidal current operation (sinusoidal current is taken from the line supply)

Combinations of the components:

</table>
6.4 Technical data

6.4.1 General information

The configuring of the infeed modules requires the performance data from the Tables 6-9 and 6-10 and the following performance curves.

![Normalized power graph](image)

**Note**

When connected to line supplies with voltage fluctuations below the rated voltage, the infeed should be overdimensioned corresponding to the above diagram (Fig. 6-9), otherwise this can lead to failures or defects.

**Table 6-7** Power factory at the rated power without filter

<table>
<thead>
<tr>
<th>Module</th>
<th>Operation on the line side</th>
<th>Factor cos φ (^1)</th>
<th>Factor λ</th>
</tr>
</thead>
<tbody>
<tr>
<td>I/R</td>
<td>Sinusoidal current operation</td>
<td>cos φ ≈ 0.98</td>
<td>λ ≈ 0.97</td>
</tr>
<tr>

<td>Squarewave current operation</td>
<td>cos φ ≈ 0.98</td>
<td>λ ≈ 0.89</td>
</tr>
<tr>
<td>UE</td>
<td>–</td>
<td>cos φ ≈ 0.87</td>
<td>λ ≈ 0.67</td>
</tr>
</tbody>
</table>

cos φ: The power factor only contains the basic fundamental
λ:  The power factor contains the basic fundamental and harmonic components
\(^1\): Is valid for sinusoidal current operation at the rated voltage without filter

**Note**

With line filter, when the converter is operating at partial load, a capacitive phase shift occurs.

As line supplies in companies generally have an inductive phase shift, this capacitive component has a compensating effect in this line supply.
Supply voltage and frequency

Switches S1.1 and S1.4 (see Chapter 6.3) are used to adapt the line infeed modules to the prevailing line supply conditions.

The converter system is designed for operation on grounded line supplies TN–S and TN–C (IEC 60364–1 VDE 0100–300). For other line supply types, a transformer with separate windings in vector group yn on the secondary side must be connected upstream (refer to Chapter 7 for the dimensioning).

Table 6-8 Supply voltage and frequency

Note

Temperature derating, see Chapter 5.4.2.

Installation altitude derating, see Chapter 5.4.3.
6.4.2 Permissible duty cycles/derating

Nominal load duty cycles for NE modules

For a derating, it must be analyzed as to the reason why this is required, and which component is involved. For instance, if derating is required as a result of the line voltage, then for uncontrolled infeed modules, the maximum motor speed must be correspondingly adapted.

The effective load must be determined over a load period/cycle and this must be set to the ratio for the rated power of the module. The resulting weighting factor B must not exceed the factors of the associated time interval T indicated in Table 6-11. Note that the maximum $P_{\text{max}}$ must not be exceeded at any time and the derating factor, depending on the pulse frequency and/or installation altitude, must be taken into account!

As a rule of thumb, the following applies for block-type load duty cycles:

$$B = \sqrt{\frac{P_1^2 \cdot t_1 + P_2^2 \cdot t_2 + \ldots + P_k^2 \cdot t_k}{T \cdot P_n^2}}$$

- $T$: Total duration of the load duty cycle
- $P_n$: Rated power of the I/R module
- $P_1, \ldots, P_k$: Magnitude of the required power
- $t_1, \ldots, t_k$: Duration of the corresponding power
- $B$: Evaluation factor for the load duty cycle according to Table 6-11
The following applies for the rules of thumb:

- The evaluation factor $B$, calculated for the load duty cycle, must be less than the maximum values $B_{\text{max}}$ specified in Table 6-11.
- The maximum infeed power $P_{\text{max}}$ of the infeed module may not be exceeded.
- The power derating as a function of the installation altitude must be taken into account.

Table 6-11 Evaluation factor for the load duty cycle

<table>
<thead>
<tr>
<th>Total duration</th>
<th>$T \leq 10$ s</th>
<th>$10 &lt; T \leq 60$ s</th>
<th>$60 &lt; T \leq 600$ s</th>
</tr>
</thead>
<tbody>
<tr>
<td>$B_{\text{max}}$</td>
<td>1.03</td>
<td>0.90</td>
<td>0.89</td>
</tr>
</tbody>
</table>

Calculation example for a block–type load duty cycle:

Evaluation/assessment factor $B$ should be determined for the following load duty cycle:

Infeed module used: I/R 36 kW ($P_n=36$ kW; $P_{\text{max}}=70$ kW)

<table>
<thead>
<tr>
<th>$i$</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
</tr>
</thead>
<tbody>
<tr>
<td>$P$ [kW]</td>
<td>50</td>
<td>20</td>
<td>36</td>
<td>0</td>
<td>40</td>
</tr>
<tr>
<td>$t$ [s]</td>
<td>1.5</td>
<td>1</td>
<td>2</td>
<td>1.2</td>
<td>1.2</td>
</tr>
</tbody>
</table>
1. Is the maximum infeed exceeded? —> No —> OK

2. Calculating the total duration $T$

   $T = \sum t_i = t_1 + t_2 + \ldots + t_k = 1.5 \text{ s} + 1 \text{ s} + 2 \text{ s} + 1.2 \text{ s} + 1.2 \text{ s} = 6.9 \text{ s}$

3. Calculating the evaluation/assessment factor $B$

   \[
   B = \sqrt[\frac{T}{P_n^2}]{\frac{P_1^2}{t_1} + \frac{P_2^2}{t_2} + \ldots + \frac{P_k^2}{t_k}}
   \]

   \[
   B = \sqrt[\frac{6.9}{362}]{\frac{50^2}{1.5} + \frac{20^2}{1} + \frac{36^2}{2} + \frac{0^2}{1.2} + \frac{40^2}{1.2}}
   \]

   \[
   B = \sqrt[\frac{8942.4}{8662}]{3750 + 400 + 2592 + 0 + 1920}
   \]

   \[
   B = \sqrt[\frac{8942.4}{8662}]{8942.4} = 0.98
   \]

4. Check, whether $B$ is $< B_{\text{max}}$ for the calculated load duty cycle $T$

   $B = 0.98$

   $B_{\text{max}}$ for a load duty cycle less than 10 s = 1.03

   —> the load duty cycle is permissible.

---

### Installation altitude over 1000 m with limitations/secondary conditions

All of the power ratings specified apply up to an installation altitude of 1000 m above sea level. For installation altitudes $> 1000$ m above sea level, the specified power ratings must be reduced according to the derating characteristic as shown in Chapter 5.4.3. For installation altitudes $> 2000$ m, an isolating transformer must be used.

For a line supply circuit with overvoltage category III, the standard prescribes greater isolating distances at altitudes starting at 2000 m. For this reason, a non–line supply circuit must be implemented using an isolating transformer.

The isolating transformer is used for uncoupling of a line supply circuit (overvoltage category III) to form a non-line supply circuit (overvoltage category II) in which the available isolating distances are then sufficient.

See IEC 60664–1 (required for the total system).

---

### Notice

The power ratings for $P_n$, $P_{s6}$ and $P_{\text{max}}$ must be reduced (derated) in the same way.

If the power ratings are exceeded, the devices can fail prematurely.

---

### Note

For UI modules, it must be carefully observed that the braking energy fed in does not exceed the power rating of the pulsed resistor. A defect does not occur; when an overload condition occurs, the resistor is shut down.

The drive unit then goes into a fault condition, with the fault “DC link overvoltage” and the motors coast down in an uncontrolled way.

---

**Warning**

The fan may only be commissioned if it is electrically connected to the module housing (PE fan via module housing).

---

**Caution**

If the fan has the incorrect direction of rotation (refer to the arrow on the fan) then cooling is not guaranteed!
Connection for 3-phase fans

Observe the rotating field!

The motor protection circuit-breaker Q is not included in the scope of supply

Fig. 6-13 Connection for 3-phase fans
6.5 HFD reactor

General information

For the unregulated 5 kW and 10 kW infeed modules, the commutating reactor is integrated. With 28 kW, it must be external.

For connection of the regulated infeed/regenerative feedback modules to the line supply, the HF/HFD reactor tuned to 7 kHz is required (see selection Table 6-12).

The HFD reactors perform the following functions:

- To limit the harmonics fed back into the line supply
- Energy store for the step-up operation of the infeed units
- Current limiting for line supply oscillations
- Together with a damping resistor, the HFD reactors dampen the system oscillations of the converter system. The HF reactors are replaced with the HFD reactors with damping resistor because they provide increased operational reliability and a longer lifetime.

The HFD reactor should be mounted as close as possible to the line supply infeed module.

Caution

The surface of the reactors can reach high temperatures.

The 100 mm clearance above and below the components to ensure air circulation and cooling must be carefully maintained. If this is not observed, then the components could prematurely age.

Temperature-sensitive components must be located a sufficient distance away or thermally partitioned off!

Note

The connecting cables to the NE module must be kept as short as possible (max. 5 m). For lengths exceeding 1 m, twisted shielded connection lines, with the shielding contacting ground on both side, should be used. It is preferable that the cable shield is connected close to the reactor footplate, using a clamp that completely encompasses the shield.

Notice

It is not permissible to use HFD reactors in the motor cable. Operation without a damping resistor is not permissible, as high voltages (several kV) can occur if the system oscillates.

Note

If commutating reactors are used that have not been released by SIEMENS for SIMODRIVE 6SN11, harmonics or switching edges not permitted for the semiconductors can occur that can damage, disturb or early age other equipment connected to the particular line supply.

<sup>1</sup> The 300 W resistance can be used for HFD applications if the following is true after a warm–up run when all axes are shut down in a regulated way:

- After an operating period of over two hours, no temperature in excess of 150 °C may occur on the surface of the 6SN1113–1AA00–0DA0 resistor.
- This warm–up run must be repeated if the hardware configuration, e.g. motor cable lengths, is changed!

<sup>2</sup> Preferred type

<sup>3</sup> Alternative possible

**Note**

Preferably, the HFD damping resistor (6SL3100–1BE21–3AA0) should be used. It must not be connected as an external pulsed resistor on the pulsed resistor module or UI module!

The HFD damping resistor can become very hot. Consequently, it must be installed so that it cannot be touched or placed at an endangered position with an appropriate warning notice.

**Danger**

During operation and briefly after being switched off, the surfaces can reach temperatures that can cause burns and results in fires.

**Reader’s note**

For mounting information and instructions for external HFD resistors, refer to Fig. 6-14 and Chapter 6.7.3.
6.6 Monitoring module

Reader’s note

For an overview of the interfaces, refer to Section 6.2.1, Table 6-1 in the column “Terminals used” under monitoring module.

For operation of the monitoring module only on the DC link, without AC power supply, 1000 µF per monitoring module must be observed for the loading limit of the line supply.

This capacity is not included in the calculation of the permitted number of pulsed resistors, because they are de–coupled using diodes.

Fig. 6-15 Monitoring module 6SN1112–1AC01–0AA1
6.6 Monitoring module

6.6.3 Mode of operation

Parameters critical for operation are monitored in the monitoring module – these include:

- DC link voltage
- Controller power supply (± 15 V)
- 5 V voltage level

If these parameters are in the permissible operating range, then the internal prerequisites for the "Unit ready" signal are available. The module group connected to the monitoring module is enabled as soon as the external enable signals have been issued via terminals 63 (pulse enable) and 64 (drive enable). The total signal activates the "Ready" relay and can be fetched potential–free using the 74/73.2 and 73.1/72 terminals. The load capability of the contacts is 250 V AC/1 A or 30 V DC/1 A.

LEDs on the front panel of the monitoring module indicate the signal states of the monitoring circuits.

### 6.7 DC link options

#### 6.7.1 Capacitor module with 2.8 mF, 4.1 mF or 20 mF

**Description**

The capacitor modules are used to increase the DC link capacitance. This means that on one hand, a brief power failure can be buffered and on the other hand, it is also possible to store the braking energy.

A differentiation is made between the modules as follows:

- Modules with 2.8 mF and 4.1 mF → are used as dynamic energy storage devices
- Module with 20 mF → is used to buffer line supply dips

The modules are available in the following versions:

- Central modules: 4.1 mF and 20 mF
  - SIMODRIVE housing type – integrated into the system group.
- Distributed modules: 2.8 mF and 4.1 mF
  - New housing types are mounted decentral in the control cabinet and are connected to the SIMODRIVE DC link using an adapter terminal and cable.

The capacitor modules have a ready display; this is lit from a DC link voltage of approximately 300 V and above. This also means that if an internal fuse ruptures, it can be identified. This does not guarantee safe and reliable monitoring of the charge state.

The module with 2.8 mF or 4.1 mF is implemented without pre-charging circuit and can – because it is directly connected to the DC link – absorb dynamic energy and therefore operate as dynamic energy storage device. For these modules, the charge limits of the line supply modules must be carefully taken into consideration.

For the 20 mF module, the pre-charging is realized through an internal pre-charging resistor; this is designed to limit the charge current and to decouple the module from the central pre-charging function. This module cannot dynamically absorb any energy as the pre-charging resistor limits the charge current. When the power fails (line supply failure), a diode couples this capacitor battery to the system DC link so that it can be buffered by the capacitors.

---

**Note**

The capacitor modules may only be used in conjunction with the SIMODRIVE 611 line supply infeed units.

The central modules are suitable for internal and external cooling.
6.7 DC link options

**Examples for the calculation**

The storage capacity in dynamic operation and for regenerative braking is calculated as follows:

Formula: 

$$w = \frac{1}{2} \times C \times (V^2_{DC \text{ link max}} - V^2_{DC \text{ link n}})$$

Assumptions for the example:

- Capacitance of the capacitor battery: $C = 4.1 \text{ mF}$
- Rated DC link voltage: $V_{DC\text{link n}} = 600 \text{ V}$
- Maximum DC link voltage: $V_{DC\text{link max}} = 695 \text{ V}$

$$\rightarrow w = \frac{1}{2} \times 4.1 \times 10^{-3} \text{ F} \times ((695 \text{ V})^2 - (600 \text{ V})^2) = 252 \text{ Ws}$$

In addition, 252 Ws for each $C = 4.1 \text{ mF}$ module can be stored for this voltage range.
The following applies for the storage capacity of the capacitor battery when the power fails:

Formula: \[ w = \frac{1}{2} \cdot C \cdot \left( V_{\text{DC link n}}^2 - V_{\text{DC link min}}^2 \right) \]

Assumptions for the example:

- Capacitance of the capacitor battery \( C = 20 \, \text{mF} \)
- Rated DC link voltage \( V_{\text{DC link n}} = 600 \, \text{V} \)
- Minimum DC link voltage \( V_{\text{DC link min}} = 350 \, \text{V} \)

\[ w = \frac{1}{2} \cdot 20 \cdot 10^{-3} \, \text{F} \cdot \left( (600 \, \text{V})^2 - (350 \, \text{V})^2 \right) = 2375 \, \text{Ws} \]

For this voltage range, a 20 mF capacitor module can supply energy for 2375 Ws.

**Notice**

\( V_{\text{DC link min}} \) must be \( \geq 350 \, \text{V} \).

For voltages below 350 V, the switched–mode power supply for the electronics shuts down.

The possible buffer time \( t_0 \) is calculated as follows with the output DC link power \( P_{\text{DC link}} \):

\[ t_0 = \frac{w}{P_{\text{DC link}}} \]

**Dynamic energy**

The DC link capacitors should be considered as being a battery. The capacitance and, thus, the storage capacity are increased as a result of the capacitor module.

In order to evaluate the required capacitance for a specific requirement in a certain application, the energy flow must be determined.

The energy flow depends on the following:

- All moved masses and moments of inertia
- Velocity, speed (and their change, acceleration, deceleration)
- Efficiencies: Mechanical system, gear units, motors, inverters (driving/braking)
- Back–up duration, buffering
- DC link voltage and the permissible change, output value, upper/lower limit value.

In practice, often there is no precise data about the mechanical system. If the mechanical system data is determined using rough calculations or estimated values, then the capacitance of the DC link capacitors required can only be determined during tests performed during the commissioning phase.
The energy for dynamic operations is obtained as follows:

The following applies for braking or accelerating operations within time $t_V$ of a drive from one speed/velocity to another:

$$w = \frac{1}{2} \cdot P \cdot t_V$$

For rotary drives with

$$P = \frac{M_{\text{mot}} \cdot (n_{\text{mot max}} - n_{\text{mot min}})}{9550} \cdot \eta_G$$

For linear drives with

$$P = F_{\text{mot}} \cdot (V_{\text{mot max}} - V_{\text{mot min}}) \cdot 10^{-3} \cdot \eta_G$$

with $\eta_G$:

- Braking $\eta_G = \eta_M \cdot \eta_{\text{INV}}$
- Acceleration $\eta_G = 1/(\eta_M \cdot \eta_{\text{INV}})$

| $w$ [Ws] | Energy |
| $P$ [kW] | Motor power |
| $t_V$ [s] | Time of the operation |
| $M_{\text{mot}}$ [Nm] | Max. motor torque when braking or accelerating |
| $F_{\text{mot}}$ [N] | Max. motor force when braking or accelerating |
| $n_{\text{mot max}}$ [RPM] | Max. speed at the start or end of the operation |
| $n_{\text{mot min}}$ [RPM] | Min. speed at the start or end of the operation |
| $v_{\text{mot max}}$ [m/s] | Max. velocity at the start or end of the operation |
| $v_{\text{mot min}}$ [m/s] | Min. velocity at the start or end of the operation |
| $\eta_G$ | Total efficiency |
| $\eta_M$ | Motor efficiency |
| $\eta_{\text{INV}}$ | Inverter efficiency |

Torque $M$ and force $F$ depend on the moved masses, the load, and the acceleration in the system.

If precise data is not available for the previously specified factors, then generally rated/nominal data is used instead.

**Engineering information**

The central capacitor module should preferably be located at the end of the system group. The connection is made using the DC link busbar.
Fig. 6-20  Mounting location for the capacitor modules

Depending on the line infeed used, several capacitor modules can be connected in parallel.

For the capacitor modules with 2.8 mF and 4.1 mF, the total charge limit of the line infeed may not be exceeded (refer to Chapter 1.3).

Capacitor modules that can be connected

The capacitor modules 2.8 mF and 4.1 mF (central/distributed) must be dimensioned/selected corresponding to the engineering table 1-4 in Chapter 1.3.5 taking into account the charge limits of the infeed.

The 20 mF capacitor modules do not have to be taken into account in the 1-4 engineering table. They must be selected as required taking into account the maximum number from Table 6-19.

</tr>
</tbody>
</table>

If there is a pulsed resistor in the system, in order to reduce the discharge time after opening terminal 48, the DC link can be quickly discharged via terminals X221:19 and 50 (jumpers). In this case, the electronics power supply must be implemented using a 3-phase line supply connection; this is not disconnected while discharging.

**Note**

Discharge through a pulsed resistor is not possible for a 5 kW UI!

**Warning**

The pulsed resistor modules can only convert a certain amount of energy into heat (refer to Table 6-24). The energy available to be converted depends on the voltage.

A monitoring function protects the resistance against overload. If this responds, then no additional energy is converted into heat in the resistor.

**Caution**

In order to avoid damage to the infeed circuit of the NE modules, when controlling/energizing terminal X221 T.19/50, it should be ensured that terminal 48 of the NE module is deenergized (the module is electrically isolated from the line supply).

The feedback signal contacts of the main contactor of the NE module must be evaluated to check whether the contactor has actually dropped out (X161 terminal 111, terminal 113 and terminal 213).
6.7.2 Pulsed resistor module and unregulated line supply infeed with pulsed resistor

The pulsed resistor module (PR module) protects the DC link from overvoltage, which, for example, would occur for UI modules when braking or for I/R modules when the power fails when stopping. The possible braking power of the total system can be increased by using one or more pulsed resistor modules.

The pulsed resistor module can be used to quickly discharge the DC link.

If the pulsed resistor (PR) module is supplied from a monitoring module, the electronics power supply must be implemented with a 3-phase AC supply system. Fast discharge is not possible if the electronics power supply is exclusively implemented through the DC link (P500/N500).

If heat-sensitive components, e.g. cable ducts, are located above the module with a clearance < 500 mm, then an air baffle plate must be provided (Order No. 6SN1162-0BA01-0AA0).

As a result of the universal housing design of the pulsed resistor module, this can be used both for internally as well as externally cooled module groups.

The UI and PR modules are equipped with a switch-on time monitoring; this protects the pulsed resistor from overheating.

The switch-in and switch-out thresholds depend on the setting of the line infeed switch S 1.1 or S 1.4, see Chapter 6.3.

2) The first data is used for pin–type cable lug. The second data is used for finely–stranded conductors without end sleeve.

### Number of pulsed resistors used on the same DC link

The following condition must be fulfilled:

\[
T = \frac{R_{SN} \cdot C_{DC\ link}}{C_{DC\ link} \geq 7.5 \text{ ms}}
\]

\[
1/R_{SN} = 1/R_1 + 1/R_2 + 1/R_3 + \ldots + 1/R_n
\]

\[
R_{SN} \quad \text{Resistance of the parallel–connected resistors in the system (15 ohm/resistor)}
\]

\[
C_{DC\ link} [\mu F] \quad \text{Total of all DC link capacities of the drive group}
\]

Secondary condition:

\[
C_{DC\ link} \text{ with pulsed resistor of at least 500 } \mu F \text{ per resistor}
\]

### Note

For a module group with pulsed resistor modules, they must be operated on the same power supply (device bus) of the I/R or monitoring module to ensure a simultaneous activation and deactivation of the resistors. Otherwise individual resistors/pulsed resistance modules can be overloaded.

For UI modules that use the integrated pulsed resistors, additional pulsed resistor modules must be operated on the device bus (PS) of the UI module!

An additional pulsed resistor module is not permitted for the 5 kW UI module!
6.7.3  External pulsed resistors

With externally attached pulsed resistors, the power loss of the resistor that occurs during braking accumulates outside the control cabinet and, thus, does not place a thermal load on the control cabinet.

The external pulsed resistors are generally required for the 28 kW UI module. Depending on the power requirement, up to two equal pulsed resistors can be connected in the case of the 28 kW UI module. The protection function is parameterized via the connecting terminals.

<sup>1)</sup> External PR can also be used for damping after a protecting measurement on the HFD reactor.
Vertical mounting is absolutely required.

**Caution**

**Risk of burning due to high surface temperatures**
The pulsed resistor can become very hot. Touching the surface can cause severe burns.

- Mount the pulsed resistor in such a way that contact is impossible. In case this is not possible, it is essential to mount a protection against contact. On endangered parts suitable warning signs must be attached clearly visible and easily comprehensible.
- To prevent damage on nearby components due to high temperatures, ensure a ventilation clearance of 100 mm around the pulsed resistor.

---

**Fig. 6-23** Connection for external pulsed resistor 0.3/25 kW

- red, blue, PE (green yellow), each 1.5 mm²
- Shielded 3 m connecting cable, can be extended up to max. 10 m

¹) As a result of the mechanical dimensions, the resistor can absorb a relatively high level of energy.

The following conditions must be fulfilled:

1. \( P_{\text{max}} \geq M \cdot 2 \cdot \pi \cdot n/60 \)
2. \( E_{\text{max}} \geq E; E = J \cdot [(2 \cdot \pi \cdot n_2/60)^2 - (2 \cdot \pi \cdot n_1/60)^2]/2 \)
3. \( P_n \geq E/T \)

Line Supply Connection

7.1 Line supply connection conditions for line supply infeed

Supply voltage and frequency

For technical data, refer to Chapter 6.4 and Tables 7-1/7-2.

Compatibility/noise immunity

SIMODRIVE infeed units are designed to be connected to line supplies with compatibility level, Class 3 of electromagnetic environments in industrial plants and systems according to IEC/DIN EN61000–2–4:2002.

When the EMC mounting/installation guidelines are complied with, noise immunity values according to IEC/DIN EN61000–6–2 Electromagnetic Compatibility (EMC) – Generic Standard, Noise Immunity/emission – Part 2: Industrial environments (1999) are complied with.

The SIMODRIVE unit may be directly connected to TN line supplies with selectively tripping, AC/DC–sensitive RCCBs as protective measure.

Upstream devices providing protection against hazardous leakage currents or for fire protection (such as residual–current protective devices) must be universal current–sensitive in accordance with the requirements of DIN EN 50178. In the case of other residual–current protective devices, a transformer with separate windings must be connected upstream of the converter for purposes of decoupling.

Fig. 7-1 Residual–current circuit–breaker (RCCB) connection schematic
7 Line Supply Connection

7.1 Line supply connection conditions for line supply infeed

Note
If a fault current protective device is used on the line supply side of this electronic device for protection in case of direct or indirect contact, only Type B is permitted! Otherwise, another protection measure must be applied, such as separating the electronic device from the environment through double/reinforced insulation or separating the electronic device from the line supply through a transformer.

Note
Points to bear in mind:
• It is only permissible to use a delayed–tripping, (selective) AC/DC current–sensitive residual–current protective device (RCCB) (connection as shown in Fig. 7-1).
• Parts of the electrical equipment and machine that can be touched are integrated in a protective grounding system.
• It is not possible to connect RCCBs in series in order to implement selective tripping.
• The max. permissible ground resistance of the "selective protection device" must be observed (83 Ω max. for RCCBs with a rated differential current $I_{\Delta n} = 0.3$ A).
• The total length of the shielded power cables used in the drive group (motor cable, incl. supply cables from supply system filters to the NE connection terminals) is less than 350/500 m for sinusoidal/squarewave current.
• Operation is only permitted with line filters. Only the line filters described in Chapter 7 may be used.

Notice
The currently widely established AC or pulse–current sensitive Type A are definitely not suitable!

Recommendation
For selective, AC/DC-sensitive residual-current protective devices offered by Siemens that comply with DIN VDE 0100 T480 and EN 50178, i.e. Series 5SM3 646–4 short-time delayed or Series 5SM3 646–5 selective with auxiliary disconnector (1 NC/1 NO) for rated current of 63 A, rated fault current $I_{\Delta n} = 0.3$ A, see Catalog "BETA Modular Installation Devices–ETB1")
7 Line Supply Connection

7.1 Line supply connection conditions for line supply infeed

When the requirements regarding system fault level are observed and when using the appropriate line supply filters, the harmonics fed back into the line supply lie below the compatibility level of Class 3 of the electromagnetic environment of industrial plants and systems according to EN61000–2–4:2002.

When the recommended SIEMENS line filter is used and the EMC mounting/installation regulations are complied with, the noise emission limits according to EN50081–2 Electromagnetic Compatibility (EMC) – Generic Standard, Noise Immunity/emission – Part 2: Industrial environments (1993) are complied with.

Notice

If line filters are used that SIEMENS has not certified for use with SIMODRIVE 6SN11xx/6SLxx, this can result in harmonics being fed back into the line supply. These harmonics can damage/disturb other equipment connected to this line supply. Certification, e.g. CE is invalid.

Certificates from Siemens are invalid, for example CE, UL. You are responsible for generating/obtaining the certificates for this new combination.

It is not permissible to connect additional loads after the line filter.

Table 7-1 Line supply connection conditions for NE modules

<table>
<thead>
<tr>
<th>Module</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>The NE modules are designed for symmetrical 3–phase line supplies with grounded neutral point: TN systems. No further consumers with asymmetric load (single-phase) may be connected for transformers with non-loadable neutral point. The line supply specifications according to EN 50178 are complied with as a result of the series (upstream) line reactor (for 5 kW and 10 kW UI, these are integrated in the module). Notice The described minimum line supply fault level is needed to trigger the fuses in the case of ground fault and short-circuit within the prescribed time in order to protect the plant and prevent damage and faults at other devices. An insufficient system fault level (short-circuit power) increases the triggering and also prevents the triggering of the fuses. This can cause, for example, arcs with the consequent fire of danger. The following applies for several converters connected to one line supply: The SK of the line supply must as a minimum, be sufficient for the highest rating converter connected to it. When selecting and dimensioning the protective elements, Chapter 7.3 must be carefully observed! The required apparent power of the line supply for each NE module is Sn = Pn ( \times 1.27 ). When operating one infeed alone on a matching transformer, as a minimum, an SK of 0.73 times the value from the table is permissible.</td>

No ground faults

Before powering–up the system for the first time, the cabinet wiring, the motor/encoder feeder cables and DC link connections must be carefully checked to ensure that there are no ground faults.
Overvoltage limiter module

Application

The overvoltage limiter module limits overvoltages at the line supply input to acceptable values. These overvoltages can occur, e.g. due to switching operations at inductive loads and line supply matching transformers. The overvoltage limiting module is used for upstream transformers or for line supplies that are not in conformance with IEC (unstable line supplies) or in line supplies where frequently switching operations occur, e.g. involving larger motors (from approx. 30 kW). The overvoltage limiting module is mandatory if the NE module is to be used in conformance with UL.

For NE modules from 10 kW and higher (100 mm wide), the overvoltage limiting module can be inserted at interface X181.

For the 5 kW overvoltage limiting module, an appropriate protective circuit is already integrated as standard.

Note

It is absolutely necessary to use the overvoltage limiting module:

- For line supplies in which higher power loads are directly connected (depending on the line supply stiffness and extent of the line supply, already necessary from 20 kW and above), and if
- Line supplies, that do not reliably fulfill the line supply specifications according to IEC–EN 61000–2–4.

</tr>
<tr>
<td>Order number</td>
<td>6SN11 11–0AB00–0AA0</td>
</tr>
</tbody>
</table>

Rated conditions

The following operating conditions apply:

- A voltage limiter must be used when transformers are used in front of the NE module.
- This limits the voltage for overvoltage condition caused by switching operations, when the line supply frequently fails, for arcing etc.
- Plants and systems that are to fulfill UL/CSA requirements must be equipped with overvoltage limiter modules.
- To protect the devices against line–side overvoltages, it is recommended that an overvoltage protection device is used directly at the supply point, in front of the main switch.

Note

For installations acc. to Canadian requirements, an external surge protective device is to be installed upstream of the power supply input of the product. This shall be a UL listed (VZCA/7) Surge Supressor Type 2 SPD, rated nominal minimum 480 V AC, damping voltage 3000 V or less, or an equivalent type.
7 Line Supply Connection

7.1 Line supply connection conditions for line supply infeed

Assembly

1. Disconnect the equipment from the power source and ensure that it is in a no–voltage condition.
2. Withdraw connector X181 from the NE module.
3. Insert the overvoltage limiter module into connector X181 up to its endstop.
4. Insert connector X181 onto the overvoltage limiter module.

Notice

If the system is subject to a high–voltage test, then the overvoltage limiting module must be withdrawn in order to prevent the voltage limiting function from responding.
7.2 Voltage matching

7.2.1 General

A distinction is made between:

- Line connection components to be directly connected to the line supply
- Line connection components to be directly connected to an autotransformer
- Line connection components to be directly connected to an isolating transformer

7.2.2 Line supply types

The air and creepage distances in the SIMODRIVE 611 drive converter system have been dimensioned for rated voltages up to 520 V AC, 300 V phase–grounded neutral point. This voltage may never be exceeded as otherwise the converter insulation system would be damaged and would result in inadmissibly high touch voltages.

Caution

The drive converters may only be connected to TN line supplies, either directly or through an autotransformer.

The SIMODRIVE 611 drive converter system is insulated in compliance with DIN EN 61800–5–x. This means that the insulation system is designed for direct connection to a TN line supply with grounded neutral point. For all other line supply types, an isolating transformer with neutral point on the secondary side must be used upstream (in front of) the units. This transformer is used to de–couple the line supply circuit (overvoltage Category III) from a non line–supply circuit (overvoltage Category II), refer to IEC 60644–1.
Connection types

The infeed can be directly connected to a TN line supply for 3–ph. 400 V AC, 3–ph. 415 V AC, 3–ph. 480 V AC. For other voltage levels, the infeed can be connected through an autotransformer.

Example:

TN–C line supply

Symmetrical 4–conductor or 5–conductor three–phase line supply with grounded neutral point with a protective and neutral conductor connector connected at the neutral point which, depending on the line supply type, uses one or several conductors.

For other line supply types 1) the NE module must be connected through an isolating transformer.

---

1) Harmonized transformer types are described in Siemens Catalog NC 60.
TT line supply

Symmetrical 3-conductor or 4-conductor three-phase line supply with a directly grounded point. The loads are grounded, e.g. with grounds that are not electrically connected to the directly grounded point of the line supply.

Fig. 7-4  TT line supplies connection schematic
7 Line Supply Connection

7.2 Voltage matching

**IT line supply**

Symmetrical 3-conductor or 4-conductor three-phase line supply with no directly grounded point. The loads are connected, e.g. with grounds.

Fig. 7-5 IT line supplies connection schematic

Thus, within the pulsed transistor converter, the voltage stressing on the insulating clearances between the power circuits at the line supply potential and the open and closed-loop control circuits referred to the protective conductor potential, according to a rated voltage of 300 V complies with IEC/DIN EN 50178.

Due to the 6-pulse 3-phase bridge circuit in the line supply infeed module, any fault currents will contain DC components. This must be taken into consideration when selecting/dimensioning a fault current protective device, e.g. an RCCB.
7.2.3 Minimum cross–sections for PE (protective conductor)/equipotential bonding conductor

Table 7-4 Minimum cross–sections for PE (protective conductor)

### 7.2 Voltage matching

#### 7.2.4 Transformers

For the assignment of transformers (auto/isolating transformers) with supply voltages of 3–ph. 220 V AC to 3–ph. 575 V AC to the NE modules, refer to Sections 7.3.2 to 7.3.4.

**Fig. 7-6 Connection schematic, matching transformer**

**Vector group**

Suggestion: Dyn0 or Yyn0; this means either a delta or star circuit on the primary side and star circuit on the secondary side where the neutral point is brought–out. For the connection, refer to Section 7.2.2.

**Note**

Switching elements (main switch, contactors) for connecting and disconnecting the line filter must feature a max. 35 ms delay time between closing and opening individual main contacts.
A SIMODRIVE NE module and other loads/machines are connected at the matching transformer (refer to Fig. 7-7).

A matching transformer must be dimensioned for the total of all loads connected to it. The apparent power required for the NE modules must be determined and added as shown in Chapter 7.1, Table 7-1. If the transformer $S_n$ or $S_k$ is too small, this can lead to increased line voltage dips and faults in the system and in other loads at this connecting point.

The short-circuit power must be adequately dimensioned so that the overcurrent protective device reliably trips.

**Warning**

A sufficiently high system fault level (short-circuit power) is required to ensure that when a ground fault does occur, the fuses rupture in the specified time. An insufficient system fault level (short-circuit power) increases the time to trip beyond permissible levels (e.g. a fire is possible).
Sn calculation of the matching transformer for an NE module

- Condition a)
  The rated power (Sn) of the matching transformer must be:
  \[ S_{n1} = 1.27 \times P_n \text{ (I/R module \([kW]\)) \ [kVA]} \]
  Example: The minimum rated power of a matching transformer for I/R module 16/21 is 21 kVA.

- Condition b)
  In order to avoid faults and disturbances at the other loads, that are connected to the secondary side of the matching transformer, the sum of the system fault level (short–circuit power) of the plant connection and that of the matching transformer at the connection point (S_K line supply) must contain at least the values shown in Table 7-1, Chapter 7.1. Depending on the vector group of the transformers, e.g. YYn0, asymmetric loading of the N/MP may not be permitted.

Consequently, the required rated power S_n2 of the matching transformer is calculated.

\[
S_{n2} = \frac{S_K \text{ plant} \times S_K \text{ line} \times u_k}{(S_K \text{ plant} - S_K \text{ line}) \times 100} \ [kVA]
\]

This means:
- \( S_{n1}, S_{n2} \): Calculated rated power of the matching transformer
- \( u_k \): Short–circuit voltage of the matching transformer as % (see Table 7-2)
- \( S_K \): Short–circuit power.
- \( S_K \text{ plant} \): if necessary, consult the utility company
- \( S_K \text{ line} \): = at least the value contained in Chapter 7.1, Table 7-1

Note:
- The system fault level at the plant connection S_K plant plays a decisive role in dimensioning/selecting the matching transformer.
- From the rated power (S_n1 or S_n2) calculated under a) and b), the higher must be used for the matching transformer.

Examples

Matching transformer for 16/21 kW I/R module sinusoidal current:
- \( u_k \) matching transformer = 3%; \( S_K \text{ plant} = 50000 \text{ kVA} \); \( S_K \text{ line} \) for I/R 16/21 kW sinusoidal current according to Table 7-1: \( S_K \text{ line} = 1120 \times 0.73 = 820 \text{ kVA} \)

Based on a) \( S_{n1} = 1.27 \times 16 \text{ kW} = 21 \text{ kVA} \)
Based on b) Calculation of S_n2

**Case 1:**

\[
S_{n2} = \frac{50000 \times 820 \times 3}{(50000 - 820) \times 100} = 25 \text{ kVA}
\]

\( S_{n2} > S_{n1} \Rightarrow S_{n2} \) is decisive
The matching transformer requires a rated power S_n of 25 kVA at a uk of 3%.

**Case 2:**

If the uk of the matching transformer is less than, e.g. uk=1%
for otherwise unchanged conditions for Case 1:

\[
S_{n2} = \frac{50000 \times 820 \times 1}{(50000 - 820) \times 100} = 8.3 \text{ kVA}
\]

\( S_{n1} > S_{n2} \Rightarrow S_{n1} \) is decisive
The matching transformer requires an S_n rated power of 21 kVA at a uk of 1%.
Case 3:
If \( S_{\text{K plant}} \) is less, then a transformer with a higher rating must be selected, e.g. \( S_{\text{K plant}} = 3000 \text{ kVA} \); otherwise as for Case 1:
\[
S_{n2} = \frac{3000 \times 820 \times 3}{(3000 - 820) \times 100} = 34 \text{ kVA}
\]
\( S_{n2} > S_{n1} \) % \( S_{n2} \) is decisive
The matching transformer requires a rated power \( S_n \) of 34 kVA at a uk of 3%.

Case 4:
When compared to Case 3, the uk of the matching transformer is reduced to, e.g. \( \text{uk} = 1\% \):
\[
S_{n2} = \frac{3000 \times 820 \times 1}{(3000 - 820) \times 100} = 11.3 \text{ kVA}
\]
\( S_{n1} > S_{n2} \Rightarrow S_{n1} \) is decisive
The matching transformer requires a rated power \( S_n \) of 21 kVA at a uk of 1%.

**Note**
\( S_{n2} \) for the matching transformer can be reduced by reducing \( \text{uk} \).

### \( S_n \) calculation of the matching transformer for several loads

- **Condition a)**
The rated power \( (S_n) \) of the matching transformer must always be:
\[
S_{n1} \geq 1.27 \times P_n \text{ (R module \([\text{kW}]\)) [kVA]}
\]

- **Condition b)**
In order to avoid faults and disturbances at the other loads, that are connected to the secondary side of the matching transformer, the sum of the system fault level (short-circuit power) of the plant connection and that of the matching transformer at the connection point (SK line supply) must contain at least the values shown in Table 7-1, Chapter 7.1. Depending on the vector group of the transformers, e.g. YYn0, asymmetric loading of the N/MP may not be permitted.

Consequently, the required rated power \( S_{n2} \) of the matching transformer is calculated.
\[
S_{n2} = \frac{S_{\text{K plant}} \times S_{\text{K line}} \times \text{uk}}{(S_{\text{K plant}} - S_{\text{K line}}) \times 100} \text{ [kVA]}
\]

**Note:**
The system fault level at the plant connection \( S_{\text{K plant}} \) plays a decisive role in dimensioning/selecting the matching transformer.
From the rated power \( (S_{n1} \text{ or } S_{n2}) \) calculated under a) and b), the higher must be used for the matching transformer.
Examples

Matching transformer for 36/47 kW I/R module sinusoidal current:
uk matching transformer = 3%; SK_plan = 50000 kVA; SK_line I/R 36/47 kW
sinusoidal current according to Table 7-1: SK_line = 2520 kVA
based on a) \( S_{n1} = 1.27 \cdot 36 \text{ kW} = 45.72 \approx 46 \text{ kVA} \)
based on b) \( S_{n2} \) is decisive

**Case 1:**

\[
S_{n2} = \frac{50000 \cdot 2520 \cdot 3}{(50000 - 2520) \cdot 100} = 79.61 \approx 80 \text{ kVA}
\]

\( S_{n2} > S_{n1} \Rightarrow S_{n2} \) is decisive
The matching transformer requires a rated power \( S_n \) of 80 kVA at a uk of 3%.

**Case 2:**

If the uk of the matching transformer is less than, e.g. uk=1% for otherwise unchanged conditions for Case 1:

\[
S_{n2} = \frac{50000 \cdot 2520 \cdot 1}{(50000 - 2520) \cdot 100} = 26.54 = 27 \text{ kVA}
\]

\( S_{n1} > S_{n2} \Rightarrow S_{n1} \) is decisive
The matching transformer requires an Sn rated power of 46 kVA at a uk of 1%.
7.3 Overcurrent protective devices, transformers and main switch

7.3.1 Assignment of the line fuses to the NE modules

Fuses or circuit breakers are necessary to protect the cables against short-circuit/ground fault, to limit any damage to the converter, provide protection against electric shock and to avoid fire in the case of a fault. The overvoltage protective devices must be located before the terminals of the drive lineup (line filter or HFD reactor).

Danger
Overvoltage protective devices only on the primary side of a transformer, which may be possibly used, are not sufficient to protect the converter or protect against fire!

Fuses and plant conditions, such as loop resistance and short-circuit power, must be harmonized with each other so that the limit curve shown in Fig. 7-8 is not exceeded.

Circuit breakers (Table 7-6) or alternatively, fuses (Table 7-7) should be used.

The appropriate protection measure should be selected corresponding to the local situation from Table 7-5.

<table>

1) Selection aid for line supply protection measures, see Table 7-5

2) **Minimum short-circuit current**: Before connecting the machine to the line supply, the necessary minimum value must be checked using a measurement corresponding to IEC 61557–3 and documented. If the minimum short-circuit currents at the connection point are not reached, then there is a risk of fire in the case of a fault.

3) The switches are designed for high switching capacity 65 kA at 480 V. The connection terminals for the switches are also required. The following box terminals, for example, are required:
   - **for 3VL2...**: two 3VL9220–4TC31 sets (one set contains three items)
   - **for 3VL3...**: two 3VL9335–4TC31 sets (one set contains three items)
   You can find information on circuit breakers under the following link: [http://support.automation.siemens.com](http://support.automation.siemens.com)

4) In combination with the appropriate circuit-breakers.
Fuses that can be used: Sizes NH, D, DO with characteristic gL.
We recommend the following SIEMENS fuses that have no restrictions relating to the characteristic power data of the NE modules.

Table 7-7 Assignment of fusible links to the NE modules

1) Tool to select the overcurrent protective devices, see Table 7-5
2) Minimum short–circuit current: Before connecting the machine to the line supply, the necessary minimum value must be checked using a measurement corresponding to IEC 61557–3 and documented. If the minimum short–circuit currents at the connection point are not reached, then there is a risk of fire in the case of a fault.
Notice

The calculated maximum short-circuit current at the connection point is an important indicator for dimensioning the required switching capacity of protective elements, fuses/circuit breakers.

Protection elements should be dimensioned so that the maximum permissible short-circuit current can be reliably switched by the selected protection element.

The calculated minimum short-circuit current at the connection point is an important indicator for the maximum permissible tripping time of protection elements, fuses/circuit breakers.

Protection elements should be dimensioned so that at the minimum short-circuit current expected, these still reliably trip within the maximum permissible trip time specified by the device manufacturer in order to guarantee protection for personnel and avoid the risk of fire.

When connecting the machine, using a suitable measuring device (according to DIN, EN, IEC 61557–3; VDE 0413–3) at the connection point of the drive system, the short-circuit current should be determined and the overcurrent protective devices installed checked to ensure that they comply with these operating conditions.

The measuring results and installed protection elements must be documented so that they can be subsequently verified when required.

Warning

For trial operation when connected to line supplies that do not have adequate short-circuit power (system default level), the protection elements should be adapted so that they trip within approx. 10 ms in the case of a fault, as otherwise there is a risk of significant damage to the device or fire.

It is not permissible to overdimension the protection elements.

Note

The recommended circuit breakers are sufficient for a maximum short-circuit current (SCCR) < 65 kA of the drive lineup.

For line supplies that deviate from this with a smaller or higher line short-circuit power, these can or must be appropriately re-dimensioned.
7.3 Overcurrent protective devices, transformers and main switch

Note

The dotted line for AC–2 applies if there is only one single circuit with DVC A. The solid line applies if there is more than one circuit with DVC A.

For timely tripping of fuses, the loop resistance as well as the vector group of the line supply transformer being fed must satisfy the requirement that the touch voltage of the devices is switched off by the provided fuses within the permissible tripping time (see Fig. 7-8 in accordance with EN 61800–5–1 Ed. 2007).
### 7.3.2 Assigning autotransformers to the I/R modules

**Note**

If, for I/R modules, a transformer is used, this does not replace the external commutating reactor.

When using a transformer, from NE module ≥ 10 kW onwards, Order No.: 6SN1114-1500-0QA11, an overvoltage limiter module must be used (Order No.: 6SN1111-0AB00-0AA0).

### Operating conditions for all transformers

The permissible current of the transformers, reactors etc. depends on the ambient temperature and the installation altitude. The permissible current/power rating of transformers and reactors is as follows:

\[ I_{\text{in (PD)}} \text{ reduced} = c \times I_{\text{in (PD)}} \]

![Fig. 7-9 Reduction factor (derating) c](image-url)

**Note**

UI modules can be operated on TN line supplies from 360 V (with derating!) to 480 V without a matching transformer.
7.3.5 Assigning the main switches

The main switches must be chosen appropriately for the machine (scope of the installation), the supply line characteristics (voltage, short–circuit power), regional regulations for plant/machine constructors.

Recommendation:
Siemens 3LD.../3KA... switch types (as listed in the SIEMENS "Low–Voltage Switchgear" catalog)

7.3.6 Use of a leading contact for line isolating device

For various plant and system configurations the use and the correct connection of a leading contact (integrating terminal 48) for the switching element is either absolutely necessary or not required. In this connection, switching elements are:

- Power disconnectors (mains switch, line supply contactor)

**Note**

During the shutdown, to prevent damaging overvoltages that can damage parallel-operated loads, terminal 48 of the NE modules must be switched off 10 ms before deenergizing the line supply contacts.

Main switches (breakers) with leading auxiliary contact can be used to ensure that terminal 48 of the NE modules is deenergized using a leading contact.

Leading shutdown is not required for certain drive configurations.
For information refer to Section 7.3.6.
Note

If the objective is that an application is not to have a leading contact over the complete power range of the infeed modules, then this can be implemented using the following measures:

- Changing over from any present I/R modules to unregulated infeed (this is generally the case for 480 V applications).
- Deactivating the regenerative feedback if I/R modules are being used.

The I/R modules then operate as UI modules and can be operated with additional loads connected to a switching element without leading contact.

Leading contact is absolutely necessary

For the configurations that are now described, a leading contact for the switching element is absolutely necessary:

- If one or more I/R modules are connected, together with other loads, through a switching element.
- If NE modules having different power classes are connected together to one switching element. In this case, the restrictions, described on the following page, must be carefully fulfilled.

The following diagram shows two examples where a leading contact is absolutely necessary.

![Diagram showing examples of a configuration where a leading contact is required](image-url)
Leading contact is not absolutely required

**Caution**

If switching elements are used without leading contact, then it must be absolutely ensured that after powering–down and –up the NE module again, terminal 48 (start/contactor control) is deenergized in order to activate the precharging circuit. If this is not the case, then high re–charging currents (similar to short–circuit currents) can occur when powering–up again. These re–charging currents are not limited by the pre–charging circuit. This can trip the fuse or damage/destroy the NE module.

For the subsequently described configurations, it is not absolutely necessary that a leading contact is used for the switching element:

- Only one NE module is connected to the switching element.

**Caution**

When using I/R modules, no additional loads may be connected to the switching element.

- Connection of NE modules with the same power class to one switching element. In this case, the restrictions for connecting several NE modules to a switching element must be carefully observed (refer to the following page).

**Caution**

If I/R modules are connected together with UI modules to one switching element, overvoltage limiter modules must be used.

Summary

7 Line Supply Connection

7.3 Overcurrent protective devices, transformers and main switch
7.4 Line filters for I/R and UI modules

7.4.1 General information

The line filters limit the cable–borne noise and disturbances, originating from the converter units, to permissible EMC values for industrial environments. If the system is consequentially executed in–line with the Configuration Manual and the EMC Guidelines for SIMODRIVE, SINUMERIK, SIROTEC, then the prerequisites are created so that the limit values at the installation location will be in compliance with the EU Directives for EMC.

The line filters can be used both for sinusoidal current as well as squarewave current operation.

The mounting/installation and connection regulations as listed in Chapter 9.1 must be carefully observed.

For more detailed information regarding an EMC–correct design, refer also to the EMC Guidelines for SINUMERIK (Order No.: 6FC5297–0AD30–0AP1).

Other suitable measures can also be adopted to comply with the EMC limits. An EMC examination is necessary in particular cases.

Note

The line supply connection conditions as specified in Section 7.1 must always be observed. If the line supply does not comply with the requirements according to EN–/IEC 61000–2–4 Class 3, then the filters could be overloaded.

The use of a matching transformer does not mean that the HFD reactor or the line filter can be omitted.

Optional line filter rows that are coordinated with the power range are also available with the SIMODRIVE 611 digital converter system. These line filters differ with regard to the frequency range in which they reduce the conducted emissions.

Fig. 7-12 Wiring information and instructions
Wideband line filter

Wideband line filters function in the frequency range from 2 kHz to 30 MHz. Load frequency harmonics are effectively limited using a wideband line filter. They are required when sensitive loads, such as electronic power supplies, etc., are operated on the same line supply. This can prevent impairment, damage, and premature aging of these loads.

Basic line filter

Basic line filters function in the frequency range from 150 kHz to 30 MHz. This especially suppresses disturbances for radio–based services.

Safety information

Caution

The line filters are only suitable for the direct connection to TN systems. The line filters listed conduct a high leakage current over the PE conductor. A permanent PE connection for the line filter or control cabinet is required due to the high leakage current of the line filters.

Only the line filters described in this Configuration Manual should be used. Other line filters can cause line harmonics that can interfere with or damage other loads powered from the line supply.

It is not permissible to connect other loads after the line filter.

Measures according to DIN EN 61800–5–1 must be taken, e.g. a PE conductor ≥₁₀ mm² CU or fit an additional connection terminal for a PE conductor with the same cross–section as the original PE conductor.

Danger

The 100 mm clearances above and below the components must be observed. The mounting position must ensure that cool air flows vertically through the filter. This prevents thermal overloading of the filter.

A hazardous voltage will be present at the terminals for up to 30 minutes after the system has been shutdown depending on the DC link capacitance.

For this reason, opening the device or removing the cover is permitted only after 30 minutes have elapsed since the device was switched to the voltage–free state. All covers must be reattached before the line voltage is switched on.

Danger of death!
Touching live terminals, cables or device parts can result in serious injury or death!

Note

If the system is subject to a high–voltage test using AC voltage, any existing line filter must be disconnected in order to obtain a correct measurement result.
7.4.2 Wideband line filter

Description

The damping characteristics of wideband line filters not only conform with the requirements of EMC standards for the frequency range of 150 kHz to 30 MHz but also include low frequencies as of 2 kHz. As a result, these line filters have an extended function area, which means that they can, to a certain extent, be used regardless of the machine installation location and any unknown line properties (e.g. line impedance).

The Wideband Line Filters should be preferably used.

For sinusoidal current operation, the total length of the power cables from the line filter should not exceed 350 m and for square-wave current operation, should not exceed 500 m!

3) The first data applies for pin-type cable lugs, the second data applies for finely-stranded conductors without end sleeves.
4) The fuse used must have this rated current. Recommendations for the fuses, refer to Table 7-6.
7.4.3 Line Filter

Description

The line filters for UI modules attenuate frequencies in the range from 150 kHz up to 30 MHz. In conjunction with the consequential implementation of the system configuration according to the Configuration Manual and the EMC installation guideline for SIMODRIVE, SINUMERIK, SINAMICS S 120, when applying the installation guideline, the limit values at the installation location can be attained according to the EC directive EMC. The precondition is that the user takes into account the specific EMC guidelines at the installation location that may possibly apply and makes a final check. From the line filter, total cable lengths up to 500 m are possible!

7.4.4 Basic line filter for I/R modules

**Description**

The basic line filter for I/R modules are designed for use in machines in which the conducted interference in the frequency range is to be reduced in accordance with EMC regulations.

The machine manufacturer must perform the EMC–compliant CE certification for the product before it is implemented.

**Note**

The company that puts the machine on the market takes full responsibility for ensuring CE EMC conformity and that the basic line filter is used correctly. The machine manufacturer (OEM) must have the machine conformity confirmed (e.g. by the EPCOS Company; mailto: emv.labor@epcos.com).

Basic Line Filters have properties similar to line filters that are generally available. The Basic Line Filter offered by Siemens, however have the advantage that they have been system–tested and released for SIMODRIVE 611. If they are used, taking into account the secondary conditions, then the Siemens system certificates for the converter system, such as CE, UL, etc. remain valid and do not result in loss of warranty!

The Basic Line Filters can be used in accordance with the following general conditions for ensuring CE conformity with regard to cable–borne interference:

- The machine/system must only be used in industrial networks.
- No. of axes <12.
- Total cable lengths <150 m (motor cables, power supply cable between the line filter and I/R module).

**Caution**

The connections/terminals may not be interchanged:

- Incoming line supply cable to LINE/NETZ L1, L2, L3
- Outgoing cable to the line reactor to LOAD/LAST L1’, L2’, L3’

If this is not observed, the line filter could be damaged.
7 Line Supply Connection

7.4 Line filters for I/R and UI modules

Interfaces

- If the line supply and load connections are interchanged, this will immediately damage the components!
- Any mounting position, base mounting is possible. However, cooling must be guaranteed and it is not permissible to interchange the line supply and load connection!

Important Circuit Information

8.1 General information

Note
The following circuit examples, information and descriptions are of a general nature and are not binding from a legal perspective. Every system must be adapted to ensure that it is complete and is correct for the particular application.

These circuit examples are intended to support the machinery construction OEM/user when integrating the SIMODRIVE 611 drive system – from the control perspective – into the overall control concept of his machine/system.

The users are responsible for ensuring that the overall control is in compliance with the Guidelines/Standards applicable for their particular application and the safety measures, derived from the hazard analysis/risk assessment to avoid injury to personnel and damage to machine, have been appropriately engineered and implemented.

Warning
After the line isolating devices (main switch/breaker) or the line contactor have been opened, residual energy and hazardous touch voltages are still available at the power DC link of the drive group while the DC link capacitors discharge – max. 30 min. This means that these hazardous touch voltages are also available at components that are electrically connected to the DC link (terminals, cables, switching devices, motors, etc.). This must be carefully taken into consideration as part of the hazard analysis/risk assessment.

After 30 minutes, a residual voltage up to 60 V DC can still be present! Any damaged DC link covers must be replaced immediately. Operation of the plant with damaged DC link covers is not permitted!

Service personnel must ensure that the complete plant or system is actually in a no–voltage condition before they perform any service, maintenance and cleaning work!

Warning
Before the drive group is powered–up or powered–down using the line supply isolating device (main switch/breaker) or a line contactor, terminal 48 start and/or terminal 63 pulse enable must be de–energized at the NE module. This can be realized, for example, using a leading auxiliary contact at the main switch.

For specific drive configurations it may not be necessary to use a leading contact when powering–down the NE modules. For information refer to Chapter 7.3.6.
8 Important Circuit Information

8.1 General information

**Warning**

If the electronics power supply of the NE or monitoring module is connected in front of the commutating reactor directly at the line supply at the 2U1–2V1–2W1 terminals, with a six-conductor connection, then establish a connection between X181 (P500/M500) with the P600/M600 DC link as specified in Section 8.15.2!

**Warning**

In order to shutdown the system when the power fails using the DC link energy it is possible to have a connection between terminals P500/M500 and the DC link P600/M600.

**Warning**

When the NE module is connected up using a six-conductor connection, and the electronics power supply is connected directly to the line supply, the jumpers in connector X181 at the NE module, inserted when the equipment is supplied, must be removed, refer to Section 8.15.

**Warning**

The input and output side connections at the line filter may not be interchanged in order to avoid damage to the equipment.
### Warning

The grounding bar is used for high–resistance connection and balancing of the DC link to the ground. It must always remain inserted.

The grounding bar must be opened only if a high–voltage test is performed.

### Note

Electrically disconnecting the line supply from the power circuit of the drive group using the internal line contactor.

The coil circuit can be disconnected in order to reliably open (de–energize) the line contactor using external electrically isolated contacts via terminals NS1, NS2 at the NE module. The DC link is not pre–charged if the connection is missing when the unit is powered–up. The state of the contactor (whether it is open/de–energized) can be interrogated using terminals 111, 113, and 213.

The NS1, NS2 connection may only be opened if terminal 48 and/or terminal 63 are de–energized using a leading contact, or is simultaneously opened when these terminals are de–energized, refer to Section 8.7.
8.2 Infeed modules

8.2.1 Connecting several NE modules to a main switch

A maximum of six terminals 48 can be connected in parallel with one another in order to shut down a maximum of six NE modules with one leading contact of the main switch.

Maximum cable length with a 1.5 mm² cross-section: 150 m (2-wire conductor)

Connection diagram:

If enable signal terminals, e.g. terminal 663, are connected in parallel to terminal 48, then the number of NE modules must be appropriately reduced due to the higher current load connected to terminal 9.

Note

If the internal power supply at NE module 1 fails, then the remaining NE modules and drives that are connected are also inhibited. The drives "coast down" unbraked.

As an alternative to the limited current capability of the internal power supply via terminal 9, the enable voltage can be taken from an external 24 V PELV /SELV power supply.

In this case, the terminals 19 of the NE modules must be connected to the 0 V reference potential (ground) of the external power supply.
8.2.2 Application, mode of operation and connection of the line contactor

The infeed modules include an integrated line contactor that is listed in the Catalog.

The line contactor is electronically controlled (energized) via terminal 48.

In order to safely and reliably disconnect the DC link from the line supply, e.g. for stopping in an emergency situation, the coil circuit of the line contactor must additionally be interrupted via terminal NS1–NS2 using electrically isolated (floating) mechanical switching elements. This means that the electronic control has no influence when shutting down with electrical isolation. The cable routing to the connecting terminals must be safely and electrically de-coupled from the electronics.

Before or at the same time that connection NS1–NS2 is interrupted, the line contactor must always be opened using terminal 48.

The NC contact 111–213 of the line contactor, positively-driven with the power contacts, must be included in the feedback circuit of the external, safety-relevant EMERGENCY STOP switchgear combination (safety relay). This means that the function of the line contactor is cyclically monitored.

Notice

If a protective separation of the power DC link from the supply line is required, for example, work must be performed on the power unit (connect/disconnect motor), also ensure that all parallel connections to the power infeed are electrically isolated using switching contacts. In this case, a possible user-specific external connection between the electronics power supply and the power DC link must be taken into consideration.

In order to shutdown the system when the power fails using the DC link energy, it is possible to have a connection between the P500/M500 and P600/M600 terminals.

If a safe electrical separation is required for this interconnection, the electronics, also possibly the monitoring module, must also be disabled or this electronic power supply – power DC link connection must be separated safely and reliably because otherwise the electronic power supply of the power DC link can be charged from the auxiliary DC link.

In the setting-up mode (only with 1FT5 motors), the connection between the electronics power supply and the power DC link must also be disconnected.
8.2.3 Timing diagram for the ready signal in the I/R module

The diagram below shows the initial state of terminals 48, 63, and 64 (jump-ered) when the I/R module is delivered. For a description of terminals 72 to 74, see Section 6.2.5.

Fig. 8-3 Timing diagram for the ready signal in the I/R module

Switch S1.2 = OFF default setting in the I/R module "Ready signal"

A
The ready relay can only pull–in if pre–charging has been completed and the internal line contactor has pulled–in.

B
When the power fails (line supply failure), the I/R module is internally inhibited. This means that the I/R module can no longer regulate the DC link voltage which means that no braking energy can be fed back into the line supply (no regenerative feedback). The drives are not inhibited, but the ready relay drops–out after the power failure detection time with a delay that depends on the line supply impedances.

C
When the line supply is switched off using the main switch or other switching elements, ensure that the terminal 48 on the I/R module is open at least 10 ms beforehand if other external parallel loads are also present in the switchgear cabinet (see Chapter 7.3.6).
8.3 Axis expansion using a monitoring module

8.3.1 Connection example, power supply (standard)

See also Section 8.15, examples of correct and incorrect NE connection to the line supply.

2) The shutdown function is shown in a simplified fashion without the contacts of the drive–related control.

3) Time relay with delayed drop–out with auxiliary voltage, e.g. 3RP1505–1AP30, \( t_{KT} \geq \text{max. braking time of the drives after the monitoring module.} \)
8.3.3 Description of the interfaces and functions

General

The electronics power supply integrated in the NE module supplies the connected drive modules via the equipment bus; and, for the digital drive groups 611 digital, also the SINUMERIK controls 840D or 810D integrated in the group.

The number of modules that can be connected is limited. The connection power of the modules that can be connected is determined by adding the assessment factors regarding the electronics points (EP) and gating points (AP). If the power requirement exceeds the power rating of the NE module power supply, then the drive group must be expanded by one or more monitoring modules. The overall system then includes two or more electronic systems that are independent of one another.

Further, the charge limit of the DC link must be carefully observed (refer to Chapter 1.3).

Enable signals/commands or fault signals only effect the axes connected to a common equipment bus. The equipment bus is interrupted between the last axis after the NE module and the monitoring module.

Examples

- Connection example, power supply (standard) —> refer to Fig. 8-4.
  The connection example shows the three–phase connection of the monitoring modules using fuse terminals after the power connection of the NE module.
  As an alternative, the power supply of the monitoring module can also be taken from the P600/M600 power DC link through terminals P500/M500. In this case it must be taken into account that as a result of the limit imposed by the DC link pre–charging circuit in the NE module, a maximum of two monitoring modules with the associated axes may be connected. In this case it must be carefully observed that after the line contactor is opened, the DC link voltage decreases and therefore the power supply/communications to the drive modules is interrupted.
  As an alternative to fused terminals, the following circuit–breaker can be used:
    e.g. SIRIUS circuit–breaker, Order No. 3RV1011–1EA1□, (2.8–4 A )
    This should be set to between 3.5 and 4 A. Although the active current drain of the monitoring module is approx. 1 A, the rated current of the circuit–breaker should be selected somewhat higher due to the high–frequency harmonic components. When a connection cross–section of 1.5 mm² is used, this therefore guarantees adequate cable protection.
- Connection example, pulse enable —> refer to Section 8.3.2
  The axes connected after the monitoring module may only be enabled if the NE module signaled ready/fault signal. This means that the power DC link has been charged–up and the internal line contactor has been closed. Any fault signals present at the NE module must act either instantaneously or delayed, interlocked with the pulse enable terminal 63 on the monitoring modules and the subsequent axes.
8 Important Circuit Information

8.3 Axis expansion using a monitoring module

- Instantaneous shutdown, pulse enable — refer to Fig. 8-5

The ready/fault signal at terminals 72–73.1 of the NE module act directly on the pulse enable, terminal 63 at the monitoring module. If there is a line fault or a fault signal, then the ready signal is withdrawn at the NE module; this means that after the drop–out time of the ready relay, the pulses of the drives after the monitoring module are inhibited and these drives "coast down".

This interlock cannot be used, e.g. for a power failure concept – and also it can disadvantages with respect to other applications when compared to a delayed shutdown.

- Delayed shutdown pulse enable — refer to Fig. 8-6

Terminal 63 at the monitoring module is also only enabled via the ready/fault signal at the NE module. If the signal is withdrawn at the NE module, terminal 63 is however only inhibited via time relay–KT with drop–out delay.

This means, for example, for a line fault or a fault signal at the NE module, under certain secondary conditions, the drives can be even more quickly braked:

- When braking, the DC link voltage must remain within the minimum and maximum monitoring limits (refer to Chapter 6.3).
- The external +24V power supply must maintain the enable signals of terminals 65, 663.
- For 611 digital drive modules, the internal enable signals must be maintained via the digital drive bus of the SINUMERIK 840D, 810D or for SIMODRIVE 611 universal, communications must be kept via PROFIBUS DP.

8.4 Drive modules

8.4.1 611 feed module with High Performance/High Standard

Fig. 8-7 Diagram showing the terminals of the VSA module with High Performance/High Standard
8.4.2 Description of the interfaces and functions

The diagram of the terminals in Fig. 8-7 shows, in a simplified form, a 2–axis 611 feed module – comprising power module, control unit with High Performance/High Standard.

Reader’s note
Control unit with digital and PROFIBUS DP interface — refer to Chapter 4.

Terminals AS1, AS2

Signaling contact, relay, start inhibit

When connecting contacts AS1/AS2 in series, a contact voltage drop up to max. 0.2 V must be taken into account for the lifetime of the contacts (100000 switching operations). For a 24 V switching voltage, due to the non–linear contact characteristics, from experience, five contacts can be simply connected in series without encountering any problems.

Terminal 663

Pulse enable/start inhibit

When terminal 663 is energized, this initiates two functions:

- The pulse enable and inhibit are effective via an optocoupler input after 1 ms for a specific axis or for 2–axis modules, for a specific module.
- The start inhibit, terminal 663 open–circuit, acts with a delay of approx. 40 ms after terminal 663 is inhibited due to the drop–out delay of the start inhibit relay.

The start inhibit supports safety–relevant functions, refer to Section 8.5.

For pulse inhibit/start inhibit, the drives "coast down" without being braked.

Switch on terminal 663 after the ready signal of the power supply (terminals 72 to 74); when stopping after a power failure, terminal 663 must remain driven by means of the voltage backup until the motors have reached a standstill.

Further, the 611D 1–axis and 2–axis modules and 611 universal HRS / HRS2 with PROFIBUS interface also have a pulse enable signal that acts on specific axes. The control is realized through NC/PLC interface signals via the digital drive bus or via the PROFIBUS DP interface. The signals are effective, delayed corresponding to the appropriate cycle times.

Terminal 9

FR+

+24 V enable voltage for the internal enable signals.

The terminal may only be used to enable the associated drive group.

Terminal 19

FR–

0 V enable voltage for the internal enable signals.
**P24 terminals**
+24 V supply for the brake control, tolerance range +18...30 V

**M24 terminals**
0 V supply for the brake control

**Terminals BE1, BE2**
Output, brake control axis 1 and axis 2, max. current is 500 mA
A UL–certified miniature fuse (max. 3.15 A) must be provided at the supply for the brake control:
Value: e.g. 3.15 AT/250 V; 5x20 mm UL
Company: Wickmann–Werke GmbH
Annenstrasse 113
58453 Witte, Germany
Order No.: 181

**Reader’s note**
Connection example for a holding brake, refer to Chapter 4.2.

**Terminals B1, B2**
Input, external zero mark (BERO), axis 1 and axis 2.
Rated operating voltage: +13 to 30 V
If the referencing of the encoder zero pulses cannot be evaluated, then a signal supplied from a mounted sensor (BERO) can be fed via this input as an “equivalent zero mark”.

**DAC assignment**
Three 8–bit digital/analog converter (DAC) channels are available. An analog image of various drive signals can be connected through to a test socket via these converters.
The three DAC channels are assigned the following drive signals by default:
DA1: Current setpoint Default shift factor: 4
DA2: Speed setpoint Default shift factor: 6
DA3: Actual speed Default shift factor: 6
M: Reference point (ground)
Resolution: 8 bits
Rated operating voltage: 0...5 V
Maximum current: 3 mA
8.5 Start inhibit in the drive modules/safe standstill

8.5.1 Start inhibit applications

The SIMODRIVE 611 drive control units support the “safe standstill” function – this provides protection against unexpected starting according to the requirements of Appendix I No. 1.2.7 of the Machinery Directive 98/37/EC, DIN EN 954–1 Category 3 and DIN EN 1037. It is important that the information and the instructions in this documentation are precisely adhered to.

For this purpose, the drive control units are provided by default with an internal safety relay with forced contacts. In the Configuration Manuals and user manuals, this safety relay is called a “start inhibit” function or “start inhibit relay.”

This safety relay galvanically separates the power supply of the optocouplers for pulse transmission to the IGBT. The connected motor can no longer generate torque.

The “safe standstill” function prevents unexpected starting of the motor (from standstill) that is connected to the drive control unit. The motor shaft is in a no-torque condition when the “safe standstill” function is active. This is the reason that this safety function should only be activated after the drive actually comes to a standstill. Otherwise, it will not be able to brake. The external machine control must have first brought the machine to a standstill and ensured that this has actually taken place (that the machine has come to a standstill).

Caution
The velocity should be zero prior to the “safe standstill” function.

Notice
When the start inhibit function is correctly used, the forced signaling contact AS1/AS2 must always be included in the line contactor circuit or the EMERGENCY STOP circuit. If the function of the start inhibit relay is not plausible regarding the operating mode of the machine, then the drive involved must be electrically isolated from the line supply, e.g. using the line contactor in the infeed module. The start inhibit and the associated operating mode may only be re-used again after the fault has been removed.
8.5.2 Mode of operation of the start inhibit

The current through the individual motor windings is controlled using the inverter power module. The motors are fed with sinusoidal current.

A pulse generation logic clocks the six power transistors in a rotating field--oriented pattern. An optocoupler for potential isolation is connected in each transistor arm between the control logic and the control (gating) amplifier of the power module.

The start inhibit acts on each specific module. In each of the drive modules, a positively--driven relay in the inverter control acts in the input circuits of the optocouplers.

A relay contact interrupts the power supply of the optocoupler inputs. This means that the optocoupler blocks and cannot transfer any signal. The pulse generation logic is inhibited using an additional branch that is electrically isolated.

For the drive modules, these two circuits are controlled from the machine control through terminal 663 (motor start inhibit). The state of the relay contact in the pulse power supply circuit is signaled to the external adaptation circuit through a positively opening contact.

The signaling contact is accessible at the module terminals AS1 and AS2 and the user can interlock this with his safety--relevant control. When the start inhibit fails, these start inhibit signaling contacts must disconnect the drive from the line supply via the power contactor in the line supply infeed (line contactor in the infeed module).
When the start inhibit circuit is activated, it is no longer possible to gate several power transistors orientated to the rotating field.

**Warning**

In the case that two faults simultaneously occur in the power module, a residual risk remains where the drive suddenly rotates through a small angle:

→ FT motors: 4 pole 90°, 6 pole 60°, 8 pole 45°;

→ Induction motors: In the retentive area, max. 1 slot division, that corresponds to approx. 5° to 15°

When a fault occurs, 1FN linear motors can continue to rotate electrically through 180° (approx. 56 or 72 mm including overshoot).

**Warning**

When the start inhibit is active, the motor can no longer generate any torque. If external forces act on the drive axes, additional holding devices and equipment are required, e.g. brakes. Here, it is especially important to note the effect of gravity on hanging/suspended axes.

The start inhibit does not result in electrical isolation. This means that under no circumstances does it provide protection against "electric shock".

For operational interruptions, maintenance, servicing and cleaning work performed on the machine or plant, the complete machine must also be electrically isolated from the line supply using the line supply isolating device, e.g. main switch (see EN 60204–1; 5.3).

### 8.5.3 Connecting–up the start inhibit

The start inhibit is addressed in the drive modules via terminal 663. The start inhibit relay is controlled using the internal enable voltage FR+ (terminal 9, +24 V) or an external +24 V voltage. When using an external voltage source, its reference potential (ground) must be connected to FR– (terminal 19).

When the relay is open, terminal 663 open, the start inhibit is activated. When the AS1/AS2 signaling contact is closed, this signals the "start inhibit is effective" state with electrical isolation.

The circuit must be protected against overload and short circuit using a fuse with a max. 2 A rating!

When terminal 663 is externally controlled (drive), a fail–safe signal must be used.
8 Important Circuit Information

8.5 Start inhibit in the drive modules/safe standstill

Notice

The start inhibit relay has pick-up and drop-out delay times of max. 40 ms. The external wiring must be connected to terminals AS1/AS2 so that it is short-circuit proof.

One side of the excitation coil of the safety relay is connected to the grounded electronics chassis (PELV circuit according to DIN VDE 0160). When supplying the excitation coil (relay coil) from an external 24 V power supply, its negative pole must be connected to ground potential. The external 24 V power supply must fulfill the requirements for a PELV circuit in compliance with DIN VDE 0160.

1) \(I = \) input; \(O = \) output; \(NC = \) NC contact
2) When the AS1/AS2 contacts are connected in series a contact resistance of approx. 0.20 Ohm must be taken into consideration over the lifetime of the contacts. For a 24 V switching voltage, due to the non-linear contact characteristics, from experience, five contacts can be simply connected in series without encountering any problems.
3) In accordance with EN 60204–1 (machine safety), control transformers must be used for AC control voltages.

Warning

Only qualified personnel may install and commission the "safe standstill" function.

All of the external safety–relevant cables, e.g. control cable for the safety relay, feedback signal contacts, must be routed so that they are protected, e.g. using cable ducts. The possibility of short–circuits and cross–circuits must be excluded.
8.5.4 Sequence and timing when using the start inhibit

The drives must have been stopped before terminal 663 is inhibited and the start inhibit is activated.

The drives can be stopped, e.g. by ramping down the drives in a controlled way using the NC program, inhibiting the drive-enable terminal 64 or the axis-specific controller enable, terminal 65.

Under fault conditions, the equipment must be safely disconnected and isolated from the line supply using the line contactor.

If a fault occurs when actuating the start inhibit, then this fault must be removed before the isolating mechanical protective devices (e.g. guards) to the working space of the machine or plant are opened. After the fault has been removed, the handling sequence for the start inhibit must be repeated. Under fault conditions, all of the drives, machine and the plant must be shutdown.

If one of the following faults occurs with terminal 663 de-energized and the protective devices withdrawn, then under all circumstances, EMERGENCY STOP must be immediately initiated:

- The feedback signaling contacts AS1/AS2 remain open; the start inhibit is not activated.
- There is a fault in the external control circuit itself.
- There is a fault in the signal cables of the feedback signal contact.

All of the drives of the machine/plant must be disconnected and isolated from the line supply via the line contactor.

If the control of the start inhibit has been correctly integrated in the external safety-relevant drive control – and has been carefully checked – the drives in the isolated working zone of the machine are secure against undesirable starting and personnel can enter or access the hazardous zone that has been restricted.

Notice

The relevant regulations for setting-up operation must be carefully observed.
8.5.5 Checking the start inhibit

The safety relay is an important component associated with the safety and availability of the machine. This is the reason that if the system functions incorrectly, the control unit together with the safety relay must be replaced. Function checks are required at regular intervals in order to detect an incorrect function.

The intervals specified in the appropriate regulation BGV A1 §39, Paragraph 3 are decisive for the intervals in which the system must be checked. This is the reason that the function check/test must be performed – depending on the application conditions; however, it must be performed at least once a year and in addition, after the system has been commissioned for the first time as well as when modifications and repairs have been made.

- The drive pulses must be inhibited when the voltage at terminal 663 is removed. Further, the feedback signal contacts AS1/AS2 of the start inhibit must close. The drive "coasts down".

- Withdrawing the protective devices, e.g. opening the protective door/guard while the drive is running. The drive must be braked as quickly as possible and then shut down. In so doing, no inadmissible hazard may occur.

- All of the possible fault/error cases that can occur must be individually simulated in the signal lines/cables between the feedback signal contacts and the external control as well as the signal evaluation functions of this control – for example, by interrupting the start inhibit monitoring circuit at terminal AS1–AS2.

- The monitoring circuit AS1 – AS2 should be disconnected for this purpose.

In all of the simulated fault situations, the line contactor must isolate all of the drives of the machine or system from the line supply.

If there is a connection between the NE or monitoring module power supply, terminal 500/M500 to the power DC link P600/M500, then this must be safely and reliably disconnected at the same time as the line contactor is opened, e.g. using contactors.

---

**Warning**

Only qualified personnel may perform these checks carefully observing the necessary safety measures.

After the start inhibit check has been completed, all of the changes made to the control as part of this check must be reversed.
8.5.6  Example "safe standstill" with contactor safety combination

![Diagram of example](image)

Fig. 8-9  Example, minimum circuitry for the "safe standstill" function with SIMODRIVE 611
Using two SIGUARD contactor safety combinations (A1, A2) for Emergency Stop and protective interlocking, it is possible to implement a configuration according to EN954–1 Control Category 3 and EN1037. Using the circuitry as shown in Fig. 8-9, a stop function, Category 1 according to EN 60204 is implemented.

Switches S2 and S3 are positively–opening position switches corresponding to EN 1088.

When the protective doors are opened, the contactor safety combinations trip, staggered in time and initiate that the drive is stopped in accordance with EN 60204–1 stop Category 1.

- Signal 0 is specified at the controller enable (CE) input of the drive by means of the enable contacts of the contactor safety combination A1. The drive is immediately decelerated to speed 0, and the pulses are canceled.

- The delay time of the contactor safety combination A1 is set so that the drive has come to a standstill when the delayed contacts open therefore initiating the second contactor safety combination A2.

- The contactor safety combination A2 instantaneously de–energizes the safety relay in the drive via terminal 663. The feedback signal contacts of the safety relay must be closed after the selected delay time has expired, otherwise the drive is isolated from the line supply via terminal 48.

- For a protective door with tumbler mechanism, the drive is stopped with subsequent pulse cancellation, e.g. by pressing an appropriate button on the machine. The “zero speed” signal releases the tumbler mechanism and when the protective doors open, the safety relay in the drive is immediately de–energized. In this particular case, the first timer stage (contactor safety combination A1) is not required.

- When the line supply is switched–in through K1 with button S1 “power on” the correct functioning of the internal line contactor of the infeed unit is checked using the feedback signal in the power–on circuit.
8.5.7  Example, "safe standstill" for several drive groups

**Function**

The concept of the "safe standstill" function with higher-level main contactor as shown in Fig. 8-10 is implemented on an electrical injection molding machine.

![Diagram](image)

Fig. 8-10  Example, "safe standstill" function with several drive groups

The machine comprises three functional drive groups. The feedback signal contacts of each control unit AS1/AS2 within a drive group are connected in series. Every drive group is secured using a moving protective device. Interdependencies according to Table 8-2 apply between the drive groups and moving protective devices.
8.5 Start inhibit in the drive modules/safe standstill

Table 8-2 Effect of the moving protective devices on the drive groups

<table>
<thead>
<tr>

<td>_</td>
</tr>
<tr>
<td>Protective door B</td>
<td>–</td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>

X = the drives are shutdown when the protective device is actuated

Behavior when the protective doors are open

As long as the assigned protective device prevents any intervention in the hazardous zone, the feedback signal contacts of these power modules are jumped. After the protective device has been opened, the drives must be shut down in the defined time and the feedback signal contacts of the safety relay must be closed – otherwise, the higher-level main contactor will open.
8.6 Application examples with SIMODRIVE 611

8.6.1 Block diagram of the application example

Fig. 8-11 Block diagram of the application example
8.6.2  Function description of the application example

Application

The block diagram, Section 8.6.1 shows an overview of an application example for a complete drive–related control of a machine with SIMODRIVE 611 drive components with analog setpoint interface.

For information on versions with SIMODRIVE 611 digital and 611 universal, refer to Section 8.8.

The individual applications and functions of the drive control are described in detail in the following Section 8.7 using circuit examples =1 to =9.

The circuit examples =1 to =3 are provided for basic machine applications. Circuit examples =1 and =4 to =9 describe all of the essential functions that are used for a processing machine/machine tool.

The circuit concept has been designed so that the individual control groups, from the basic function in circuit example =4

- Drives on/off/Stopping in an emergency situation; start/stop/save standstill through additional functions
- Operating mode selection, automatic/setup mode with agreement =5
- Protective door monitoring with tumbler mechanism =6
- Limit switch, limit position monitoring =7
- Armature short–circuit braking =8, and
- Power contactors in motor circuit =9

can be used for the particular applications, graduated from basic up to complex functions. When expanding the control system, step–by–step, up to the fully expanded configuration, the terminal jumpers, in the circuit examples, should be removed (interrupted), and the required interlocking and monitoring circuits inserted.

In the application example, Fig. 8-11 the SIMODRIVE 611 drive group comprises a 1PH7 main spindle drive and three 1FT5 feed drives as an example for a machine tool.

The drive–related control essentially includes the safety–relevant, 2–channel hardware control with the associated PLC functions. The PLC control handles the coordinated sequence of the drive control through logic operations; however it does not handle any safety–relevant functions.

The NC/FM (positioning control), with the setpoint and actual value interface as well as the machine control of the user side, is not discussed in the subsequent text. This is the reason that they are only depicted from the essential principle.

- Control Category in accordance with EN 954–1

The 2–channel system structure of controls =4 to =6 corresponds, when the individual components are correctly used, to control Category 3 according to EN 954–1. This means that if a single fault occurs in the system, then the safety function must still be kept.
The user should evaluate the control Categories of the additional circuits =7 to =9. This depends on how he uses the third–party components/monitoring devices that he selected etc. and how they are integrated into the basic control in a safety–relevant fashion.

**Note**

For machines that are to be classified in a lower Category, e.g. 1 or 2 according to EN 954–1, after the hazard analysis/risk evaluation or type C Standard, the control can be principally derived from these circuit examples and implemented in a more simple, single–channel, system structure!

This also applies to the sub–areas/sub–functions of a machine that, for example, according to type C Standards, must be implemented with either a lower or higher control category, deviating from the basic machine. For example, after the danger analysis/risk evaluation it can also be necessary that a hydraulic/ pneumatic clamping unit must be controlled in the work area using a two–handed control device in accordance with category 4.

**Functions**

- **Switching examples =4 to =9**
  
  The 2–channel system structure is achieved in this application example:
  
  First shutdown path: The power feed to the drive motors is disconnected via the start inhibit functions in the drive modules.

  The shutdown is realized using terminal 663. The positively–driven feedback signal contact of the start inhibit relay via terminal AS1–AS2 is cyclically monitored and intervenes in the EMERGENCY STOP circuit of the safety relay.

  For a detailed description of the start inhibit function, refer to Section 8.5.

  Second shutdown path: The line contactor in the NE module galvanically disconnects the line supply from the DC link of the drive modules.

  The shutdown is realized using terminal 48 at the same time (simultaneously) with the de–energizing of the contactor coil in a safety–relevant, electrically isolated fashion using terminals NS1– NS2.

  The shutdown is realized, for example, when stopping in an emergency, from fault signals received from the drive system or via the start inhibit monitoring when a fault condition occurs.

  After each power–off cycle, the forced normally closed contact 111 – 213 of the line contactor is monitored in the feedback circuit of the EMERGENCY STOP safety relay. For a detailed description of the line contactor, refer to Section 8.2.2.

  For an EMERGENCY STOP, the drives are stopped in Stop Category 1 according to EN 60204–1; 9.2.2: “Controlled stopping” – the power feed is only interrupted when the motor has come to a standstill.

  Circuit examples =2 and =3, shown in Section 8.7, can be used for basic and average applications.
• Circuit example =2:

When the drives are powered up and powered down, the complete drive group, including the line contactor and start inhibit terminals, is switched in a safety–related way through two channels. The power–on frequency per unit time of the NE module is limited. This is due to the pre–charging circuit to ramp up the DC link voltage at the capacitors.

This circuit is, for example, not suitable for machines where the protective door is frequently opened or for the "setting–up" mode where the agreement function is frequently applied.

• Circuit example =3:

Using this circuit, one or more drives can be selectively shut down in a safety–related way from an operational drive group, using a key–operated switch, limit switch, light barriers, and brought into the "safe standstill" operating mode.

Beforehand, the NC control must have safely stopped the drives. This circuit can also be used in conjunction with the basic control =4.

Circuit examples =2 and =3 are also used to obtain a basic understanding of the complex and extensive control functions from circuit =4 onwards.

Note
All of the following circuit examples neither include safety–related or other mechanical interlocks that may be necessary with the machine control on the user side.
8.6.3 Safety systems and Standards

Objectives

The objective of safety systems is to keep potential hazards for both people and the environment as low as possible by using suitable technical equipment, without restricting, more than absolutely necessary, industrial production, the use of machines and the production of chemical products. The protection of man and environment has to be put on an equal footing in all countries by applying rules and regulations that have been internationally harmonized. At the same time, this is also intended to avoid that safety requirements in different countries have an impact on the competitive situation, i.e. the intention is to facilitate international trade.

Basic principle of the legal requirements in Europe

Legislation demands, "the quality of the environment and the health of people are to be protected using preventive measures" (Directive 96/82/EC of the Council "Seveso II"). Legislation also promotes "health and safety at work" (Machinery Directive, health and safety legislation). The objective to achieve these and similar goals is specified in the appropriate EU Directives by legislative bodies for various areas ("regulated area"). In order to achieve these objectives, the legislative bodies place demands on companies operating plants and systems and the manufacturers of equipment and machines. These legislative bodies have at the same time allocated responsibility for possible damage.

EU Directives

A new concept ("new approach", "global approach") used as basis for the EU Directives:

- EU Directives only specify generally valid safety goals and define basic safety requirements.
- EU Directives specify that the Member States must mutually recognize domestic regulations.

The EU Directives are all of equal importance, i.e. if several Directives are applicable for a specific piece of equipment or machine, then the requirements of all of the relevant Directives apply.

For a machine with electrical equipment, among others, the following apply

- Machinery Directive 98/37/EC
- Low Voltage Directive 2006/95/EC
- EMC Directive 2004/108/EC

Machinery directive

The European Machinery Directive is essential valid for all machines. The minimum requirements are defined in Appendix I of the Directive. More detailed information is then provided in the harmonized European Standards – types A, B and C.
### Disposal

The devices must be disposed off corresponding to the regulations valid in the particular country!

However, Standards have not been drawn--up for all types of machines. For machine tools for metal working, robots, and automated manufacturing systems, some Draft Standards and final Standards do exist, e.g. type C Standards. In many cases, Category 3 acc. to EN 954–1 is defined in these Standards for the safety--related controls. The basic requirement of this category is: "Single–fault fail–safety with partial fault recognition". Generally, this requirement can be fulfilled using a 2–channel system structure (redundancy). Sub–areas of a machine control can also be classified with other Categories – B, 1, 2, or 4 according to EN 954–1.

### Hazard analysis and risk assessment

According to the Machinery Directive 98/37/EC, the manufacturer of a machine or a safety component or the person or persons responsible for placing such equipment on the market is legally obliged to perform a risk analysis in order to determine all of the risks that may arise in connection with the machine or safety component concerned. He must design and construct the machine or safety component on the basis of this analysis.

A risk assessment must identify all residual risks that need to be documented. For the technique to evaluate and assess these risks, among others, the following Standards should be carefully observed EN 292 "General Design Guidelines for the Safety of Machinery”; EN 1050 "Safety of Machinery, Guidelines for Risk Assessment" and EN 954 "Safety–relevant Parts of Controls”.

### CE conformity

The machinery manufacturer or the company based in the European Economic Community or persons that they have nominated must make a legal declaration regarding the CE Conformance for the complete machine.

---

**Note**

The listed Directives and legislation represent just a selection to communicate the essential goals and principles. This list does not claim to be complete.

8.7.1 Higher–level information, instructions and functions

When engineering the drive components, safety switching devices, contactors, shown in the circuit examples, it is absolutely necessary to carefully observe the associated connection information/instructions, technical data of the current Operating Instructions and Configuration Manuals as well as the appropriate Catalogs and Application Manuals.

- SIGUARD safety combinations 3TK28/3TK29; circuit examples as well as the "automatic start" and "monitored start" functions are described in the "Safety Integrated" Application Manual, Order No. 6ZB6000–0AA01–0BA1.

- SIRIUS power and auxiliary contactors 3 RT1 and 3 RH11 should be selected with positively–driven auxiliary contacts according to ZH1/457, IEC 60947–5–1.

- Contact reliability
  The auxiliary contacts, switching contacts of the switching devices and the line isolation equipment must be able to reliably switch low switching currents \( \leq 17 \text{ V, 5 mA} \).

- Overvoltage limiting
  All of the switching devices, coils, inductances, brakes, etc., must be equipped, for EMC reasons and for reasons associated with the functional safety, with RC elements, varistors, diodes or diode combinations. These are intended to dampen overvoltages at switch–off if these damping elements are not already integrated in the devices.
  This also applies to switching devices controlled from PLC outputs.

---

**Note**

The selection of the overvoltage limiting function also influences the off delay of the devices. This effect must be carefully taken into account when engineering the system.

Refer to NSK Low–Voltage Switchgear Catalog for selection and technical data.
8.7 Circuit examples =1 to =9 with SIMODRIVE 611

Definition of the terminology

“Powering–down in an emergency” EMERGENCY OFF and “Stopping in an emergency” EMERGENCY STOP

- Actions taken when an emergency arises according to EN 60204–1 (VDE 0113, Part 1): 1998–11, Section 9.2.5.4 should be interpreted as follows:

- Powering–down in an emergency: In Stop Category 0 according to EN 60204–1; 9.2.2 stopping is achieved by immediately disconnecting the power feed to the machine drive elements (i.e. uncontrolled stop). Generally, this type of power–down operation is interpreted as EMERGENCY OFF.

- Stopping in an emergency: In stop Category 1 according to EN 60204–1; 9.2.2 a system is stopped in a controlled way; in this case, the power feed to the machine drive elements is maintained in order to stop in a controlled fashion. The power feed is only interrupted when standstill has been reached. Generally, this type of stopping is defined as EMERGENCY STOP.

- In the circuit examples, when stopping in an emergency, the term EMERGENCY STOP function is used.

The EMERGENCY STOP buttons cause a shutdown according to Control Category 3 in compliance with EN 954–1 through two channels using the 3TK2806–0BB4/3TK2842–1BB42 safety relays. When required, the switching devices also allow an EMERGENCY STOP button to be connected in a configuration that is cross–fault circuit proof, Category 4 according to EN 954–1.

- Braking using terminal 64 – drive inhibit – at the current limit

By inhibiting terminal 64 – drive enable at the NE module or the monitoring module – the drives are stopped as quickly as possible at the selected current limit (torque limit)/ramp of the drive module.

- NE module regenerative feedback power

The power rating of the NE module is selected according to the rated power of the connected motors – reduced by a demand factor. When braking at the current limit, ensure that the braking power does not exceed the peak regenerative feedback power of the I/R modules (see Table 6.3) and the braking power of the pulsed resistors in the UI modules. In borderline cases, the NE modules should be dimensioned somewhat larger or additional pulsed resistor modules with external pulsed resistors should be used.

- Setpoint and actual position value interfaces

A complete drive module with power and control module with High Performance for 1FK6 motors is shown in a block diagram in Section 8.4.1. The setpoint is controlled via terminal X141. In circuit example = 1, the setpoint and actual position value interfaces of the NC control, e.g. 840D, are only shown once as a schematic sketch. These are not discussed any further in the additional circuits.

A detailed description of the control units is provided in Chapter 5.

- Motor holding brake

The holding brake must be controlled in a coordinated way with respect to time. For instance, using the PLC logic as a function of the pulse cancellation, controller enable and speed setpoint input. In this case, the times required for the holding brake to open and close must be taken into account. If the brake control is not optimally harmonized and coordinated, then this results in increased wear and premature loss of the braking performance.
In the circuit examples, for a drive stop, the holding brake is disconnected with drop-out delay using the appropriate hardware in addition to the PLC control. This means that a PLC fault cannot result in the brake being incorrectly controlled when the drive is stationary. It must be decided, on an application-for-application basis, whether when stopping in emergency, the brake is to be shutdown instantaneously or with a delay. Using an internal sequence control, 611U controls allow a holding brake to be controlled in a coordinated way (refer to the Function Description for SIMODRIVE 611 universal).

Holding brakes must be provided with external circuitry to dampen overvoltages.

For detailed description, refer to the Configuration Manual for SIMODRIVE motors.

- Safe standstill

After the drives have stopped, by safely disconnecting the power feed to the motors, the drives are in the safe standstill condition. When the start inhibit is activated, then the pulses are safely cancelled in the drive modules.

Features

- The motor cannot be started accidentally.
- The power feed to the motor is safely disconnected
- The motor is not electrically isolated from the drive module or the converter DC link.

The machinery construction OEM must take the appropriate measures to ensure that the drives do not undesirably move after the power feed has been disconnected.

Secondary conditions, e.g. for vertical/suspended axes:

- Safe standstill is only guaranteed if the kinetic energy stored in the machine cannot result in an unpredictable motion of the drives/axes. For example, for vertical or inclined axes without weight equalization, motion can occur as a result of non-symmetrical rotating bodies or workpieces.
- The motor holding brake supports the safe standstill operating mode.
- When manually intervening in the automatic mode, when traversing in setup mode, as well as during service/maintenance and repair work, depending on the hazard analysis, it may be necessary to apply additional measures for personnel and machinery protection.
- Axes can be secured from dropping/falling or axes can be locked in a specific position using redundant devices in addition to the holding brake, e.g. using electromechanical or pneumatic locking devices with cyclic monitoring.
8.7.2 Circuit example =1 "Cabinet supply, NC, PLC"

When designing, constructing and implementing the electrical/control cabinets to accommodate the drive components, the following important regulations, among others, must be carefully observed:

- DIN EN 60439–1 (VDE 0660 Part 500) 2000–08 Low–Voltage Switchgear Combination
- DIN EN 60204–1 (VDE 0113 Part 1) 1998–11 Electrical Equipment of Machines, Safety
- DIN VDE 0106 Part 100 1983–03 Protection against Electric Shock.
- EMC and Low–Voltage Directive
- Enclosure/housing degree of protection IP 54 or corresponding to the requirements of the ambient conditions.

Device selection

- Q1 line isolating device (main switch) with leading auxiliary contact when opening
  Selection, refer to Chapter 7.3.5 and Catalog NSK
  The line isolating device electrically disconnects the equipment from the power supply.

- G11 SITOP power power supply unit for 24 V DC, refer to Catalog KT 10.1.
  The power supply and the connected circuits must fulfill the requirements of PELV /SELV = function extra–low voltage with protective separation. We recommend that regulated power supply units that limit the current are used, e.g. SITOP power.

- F11–F14 miniature circuit breakers 5SX or 5SY, refer to Catalog I2.1.
  The potential assignment of the circuits has been randomly selected.
  The max. permissible values of the protective elements must, under all circumstances, be carefully observed when protecting the safety relays and circuits.

- Line fuses for the NE modules, assignment refer to Chapter 7.3.1 and Section 6.2.5.
- Line filter, refer to Chapter 7.4 and Catalog NC 60
- Line commutating reactor, refer to Chapter 6.5.1 and Catalog NC 60
8.7.3 Circuit example 8.2 "Drives on/off/stopping in an emergency"

Application
Drive group, comprising an NE module, three 611 FD modules with High Standard control boards. This circuit concept can be used, for example, for basic drive controls. When the drives are powered up and powered down, the complete drive group, including the line contactor and start inhibit terminals, is switched in a safety-related fashion through two channels.

Functions

Drives On
- Key-operated switch –S21, control on.
  The power-off circuit before the EMERGENCY STOP safety relay –K21 – with the expansion devices –K22, –K23 – must be switched-in taking into account the following conditions:
  - Contactor –K25 closes, ready signal from the NE module. (ready conditions, NE module, refer to Section 6.2.5!) When the control is powered-up, the ready signal is still not present. This means that the PLC output O25 must be set to "1" using the PLC logic so that the power-off circuit is closed through contactor –K25. After the drive group is switched in via the switching devices –K21, –K22, and –K23, the ready message is issued via PLC input I11, provided no error messages are pending. The ready monitoring is now activated in the power-off circuit by means of the PLC logic.
  The feedback circuit from contactor –K25 is monitored using PLC I25.
  - Contact =A1–A25/1–2 NC ready (ready signal) must be switched through to the NC control.
  - Interlock circuit terminal 35–36 is closed.
  - The expansion devices –K22, –K23, the line contactor, the start inhibit functions/terminals and contactor –K27 for the brake control are now monitored, at each power-on cycle for the safety-related off switching condition. When required, safety-relevant functions of the machine control on the user side can also be incorporated in the feedback circuit.
  - Pushbutton –S23, drives on
    Contactors –K21, –K22, –K23 are closed and power-up the drive group. After the DC link pre-charging has been completed, the line contactor in the NE module is closed. The ready message is issued as long as there is no error message present.

NC program, start/stop
- Pushbutton –S29/–S28
  The axis-specific controller enable signals are activated and the NC machining program is started using pushbutton –S29 NC program start. At the end of the program or using pushbutton –S28 – stop – the drives are brought to a controlled standstill.
Drives, off

Using pushbutton –S24 EMERGENCY STOP or –S22 Off, the drives, assuming that they have still not been stopped via the NC program, are braked and stopped as quickly as possible at the selected current limit of the drive modules. Terminal 64, drive enable, is inhibited and braking is initiated using the instantaneous contact of contactor –K22. After braking has been completed, the line contactor is opened using a safely overlapping shutdown time via the off delay contact of –K23 in a safety–relevant way through two channels via terminal 48 and NS1–NS2 of the line contactor; the drive inhibit functions are activated by inhibiting terminals 663. Fault signals of the drive system, interlocked using the PLC logic can be used, depending on the application, to brake along the current limit or for controlled braking along a setpoint ramp. The Off button also acts on PLC I22. This means PLC logic can be used to determine which switch–off command caused the drive group to be shutdown. The drive group can also be powered down via the PLC, logically combined, independent of the ready signal of the NE module using contactor –K25.

Holding brake

The holding brake is controlled, coordinated as far as the timing is concerned by the PLC logic through PLC O27. When the drives are stopped, the brake is additionally safely shutdown per hardware using an off delay contact of contactor –K23. This means that a PLC fault, when the drive is stationary, cannot cause the brake to be incorrectly controlled.

Temperature sensor

If the temperature monitoring is tripped because of overtemperature of a drive module and/or a motor, the 5.1–5.3 relay contact on the NE module activates the PLC–E12 input. Using the logical interlocking in the PLC, the drives must, depending on the application, be shutdown either instantaneously or delayed, e.g. using PLC O25 and contactor –K25.
8.7.4 Circuit example =3 "Drives start/stop/safe standstill"

**Application**

This control is used where one or several drives must be selectively shut down from an operational drive group using safety–relevant technology. The drive can be shutdown in a safety–relevant way from the drive group using a two–channel key–operated switch or, e.g. using light barriers or limit switches. Beforehand, the drive must have been safely stopped by the NC control. The "safe standstill" condition is achieved using the start inhibit function.

**Functions**

**Drives, start**

The drive is moved and stopped in a controlled way using the NC program.

**Stop drives**

Safety relay –K11 is de–energized using key–operated switch –S11 or when EMERGENCY STOP is pressed. The instantaneous contact withdraws terminal 65 "controller enable" and the drive is braked at the current limit. Terminal 663 is de–energized via the off delay contact –K11 and therefore the start inhibit activated.

**Start inhibit monitoring function**

The start inhibit monitoring function for terminals 35–36 is effective in the EMERGENCY STOP circuit of contactor =K2–K21.

Normally, when a drive is stopped, the NC contact AS1–AS2 of the start inhibit relay should always be closed before the NO contact of contactor –K13 opens. To ensure this, the contactor coil –K13 must be equipped with a diode to extend the contactor off delay. If the start inhibit function is incorrect, the monitoring circuit opens and disconnects the complete drive group through the line contactor.

The start inhibit is actively monitored in a cyclic manner after every stop operation.

**Holding brake**

The function is similar to that in circuit example =2
8.7.5 Circuit example =4 "Drives, on/off/stopping in an emergency; start/stop/safe standstill"

Application
Drive group, comprising an NE module, MSD module for 1PH7 motor and three FD modules 611 with High Standard control boards. Circuit =4 is the basic circuit for the drive-related control, e.g. of a machine tool. Using the subsequent circuit components =5 to =9 with the necessary interlock and monitoring circuits and the application-specific supplements, the control can be expanded in a modular way and therefore individually adapted to the particular application.

Functions

Drives, on (NE module)
- Key-operated switch –S21, control on.
  The power-off circuit in front of the EMERGENCY STOP safety switching device –K21 must be closed under the following conditions:
- The interlocking circuits of the following expansions of circuit =7 are jumpered.
- Contactor –K25 closes and contact =A1–A25/1–2 NC ready is closed. The power-on conditions are almost comparable to circuit =2. The additional function is that the ready signal of the MSD module – PLC I15 must be interlocked in the PLC in addition to the ready signal of the NE module – PLC I11.
- Pushbutton –S23, drives on
  Contactor –K21 closes and latches. Initially, only the NE module is powered up. After the DC link pre-charging has been completed, the line contactor is closed. The ready signal is issued as long as there is no fault signal at the NE module and at the FD modules (switch, ready/fault signal is set to fault signal).

Drives, start (drive modules)
- The NE module must be powered up. The stop circuit in front of safety relay –K31 must be closed. The interlocking circuits of the following expansions of circuit =5 are jumpered.
- Simultaneously, terminal 63 central pulse enable, terminal 64 "drive enable" at the NE module and terminal 663 "pulse enables " for the drive modules are energized and therefore the start inhibit functions are withdrawn.

NC program, start/stop
- Pushbutton –S29/–S28
  The axis-specific controller enable signals are activated and the machining program is started using pushbutton –S29 NC program start. At the end of the program or using pushbutton –S28 – stop – the drives are brought to a controlled standstill.
8.7 Circuit examples =1 to =9 with SIMODRIVE 611

Stop drives

- Using the two–channel pushbutton –S31, drives stop – the drives are braked and stopped as quickly as possible at the selected current limit of the drive modules if these have not already been stopped by the NC program.

- Terminal 64 – drive enable – is de–energized by the instantaneous contact of contactor –K31. After the drives have come to a standstill, terminal 663 is inhibited and the start inhibit functions become active via the off delay contacts of the safety relays –K32 and –K35.

- The shutdown times are adapted to the various braking times of the MSD and FD drives and must safely overlap these from a time perspective, e.g. MSD 5 s; FD 0.5 s.

Start inhibit monitoring function

The start inhibit monitoring function for terminals 37–38 is effective in the EMERGENCY STOP circuit of contactor –K21. Normally, when the drives stop, the NC contacts AS1–AS2 of the start inhibit relays in the drive modules must always be closed before the NO contact of contactors –K33 and –K36 open. In order to realize this, the coils of these contactors must be equipped with a diode to extend the contactor drop–out delay. If the start inhibit function is incorrect, the monitoring circuit opens, EMERGENCY STOP contactor –K21 drops out and shuts down the complete drive group through the line contactor. The start inhibits are actively monitored in a cyclic manner after every stop operation.

Drives Off

- Using the EMERGENCY STOP pushbutton –S24 or Off –S22 – the drives are braked and stopped as quickly as possible at the current limit. The function is similar in circuit diagram =2. After the braking time of the spindle drive, the –K31/–K32 contactor is used to switch off the drive group, i.e. line contactor off and start inhibits active.

Holding brake

The control is similar to circuit example =2

Temperature sensor

The function is similar to circuit example =2

In addition, the temperature monitoring function of the spindle drive must be evaluated via PLC I13 and –I14.
8.7.6 Circuit example =5 "Drives, operating modes automatic operation/setting-up operation with agreement"

Application

The operating mode changeover is used for most machines/plants, e.g. in setup mode, in order to traverse/operate sub–functions of the machine at a controlled, reduced velocity. In this particular operating mode, other sub–areas must be shutdown in a safety–related way to avoid potential hazards. The drives can only be operated with an agreement issued by the operator in the setting–up mode with reduced velocity/speed. This agreement can, for example, depending on the risk assessment, be issued from a secure location outside the hazardous zone of the machine or using a mobile hand–held unit with additional EMERGENCY STOP pushbutton in the operating zone of the machine.

Notice

In this case, the user is responsible for observing and complying with the specific technological and machine–specific regulations and standards to maintain the protection and safety of personnel and machinery. Further, residual risks must be evaluated – those risks that are due for example to vertical axes.

The start phase of the machine after power–on is especially critical. An agreement for a specific traversing motion should only be issued if the machine had previously moved in a controlled way.

Functions

Operating modes

The operating mode selector switch –S15 must be able to be locked as a key–operated switch or must be implemented in another way so that it can be locked–out.

Notice

The operating mode may only be changed when the drives are stationary and this must not result in a hazardous situation at the machine.

AUTOMATIC mode

Key–operated switch –S15 is set to automatic, contactor –K15 pulls–in. The monitoring circuit, drives stop in front of contactor =4–K31 is closed via terminals 53–54/55–56. This means that the drives can be started under the power–on conditions specified in circuit example =4, using the pushbutton, drives, Start =4–S32.
Set-up operation

Key-operated switch –S15 is set to setting–up, contactor –K15 drops–out, contactor –K16 closes. The monitoring circuits terminals 53–54/55–56 are open. This means that the drives cannot be started. When the monitoring circuit, terminals 511–512 is opened, pushbutton =4–S32 – Start drives is ineffective in the setting–up mode.

Using the interlocking circuit terminals 57–58, the drop–out delay for contactor =4–K32, used for the shutdown time of the spindle drive is changed–over from 5 s, for example, to the shorter time of the FD drives, for example, 0.5 s. If a fault condition is present this means that the complete drive group is already shutdown after this shorter time. Further, with the changeover to setting–up, the speed setpoint for the drives is reduced via PLC I18. The speeds and feed velocities are therefore to be reduced to permissible values according to the type C Standard or the hazard analysis.

Notice
Setpoint limiting is not a safety–relevant function.

Agreement function

The safety relay –K11 and contactors –K13/–K14 are switched–in – if the feedback circuit is closed – using pushbutton –S11 – agreement (pushbutton with two positions).

The interlocking circuit is then closed through terminals 53–54/55–56. A start pulse must be generated via PLC I17 with a time delay >= 80 ms; this pulse is output at PLC O17. Contactor –K17 briefly pulls–in and issues the start commands for contactors =4–K31, –K32, –K33, –K35 and –K36 through terminals 51–52.

The start inhibit functions are withdrawn and therefore the drives are enabled in a safety–relevant way – as long as the agreement button is pressed.

Using the non safety–relevant PLC function keys – in conjunction with the hardware agreement function – the selected drives can now be individually traversed with reduced parameters.

Notice
No motion may be started by just pressing the agreement button alone. Note: When terminal 81 – ramp–function generator fast stop – is withdrawn, after every agreement command, the spindle induction motor must be re–magnetized and therefore starts with some delay ≥ 0.5 s.

If hazardous operating states exist, if the PLC function keys fail, or for any other unpredictable situation, the drives can be stopped in a safety–related way by releasing the agreement button.
Notice

For dynamic drives with inadmissible speed increases, potential hazards can occur under fault conditions due to the response times of personnel and the delay when the agreement device switches. These hazards must be reduced by applying additional measures, e.g. a safety–related speed monitoring function. Various type C Standards, e.g. for machine tools, specify a safely monitored speed in the setting–up mode for spindle drives.
**Application**

In the automatic mode, the working zone of a machine is isolated using a moving, closed protective door (e.g. guard). In the circuit example, the protective door is interlocked and cannot be opened while the drives are running or if other hazardous operating states exist. This is realized using a position switch with tumbler mechanism with an interlock using spring force with sealed auxiliary release. Automatic operation for the drives is only enabled if the protective door is closed and interlocked via the position switch.

Depending on the hazard analysis, the user must decide whether, e.g. a second limit switch is additionally required for the door monitoring function.

The protective door is prevented from being opened as long as a hazardous state exists, e.g. as a result of the drives running–down. The enable signal is only issued with a time delay after the drive with the longest braking time has been reliably and safely stopped or optionally using the standstill signal of an external speed monitoring function.

For several applications, e.g. if personnel can enter the working area of a machine, the tumbler mechanism of the protective door is implemented using a position switch interlocked with magnetic force. This is for safety–related reasons. When the line supply or control voltage fails, the position switch can be used to release the protective door and allow it to be opened.

**Functions**

**Request protective door enable**

The drives must initially be shutdown using pushbutton =4–S31 – stop drives – or optionally, e.g. at the end of the NC program by the output of an NC auxiliary function, PLC O18 closes contactor –K18.

The protective door enable is requested using pushbutton –S15. Contactor –K15 is activated, interlocked through the PLC logic when the drives are stopped and shut down. This means that contactors =4–K33 and =4–K36 have dropped out. PLC logic: PLC O15 = "1", if =4–I33 and =4–I36 = "0" signal.

When requesting that the protective door is enabled, in the secured working zone of the machine/plant, all hazardous motion and other potential hazards of the user–side machine control must be shutdown. The shutdown must then realized in a safety–relevant way using the released or opened protective door.

**Releasing the protective door**

The protective door is released using contactor –K16 if the following conditions are fulfilled:

- Contactor –K15 is closed (energized)
- Drives, delayed stop, contactors =4–K33 and =4–K36 open (de–energized).
- MSD standstill signal n act < n min via relay =4–K11.
- User–side interlocking circuit is closed via terminal 601–602.
Optional:

- External standstill monitoring closed via terminal 77–78.

The interlocking solenoid of the door position switch –S11 is energized and the safety relay –K11 and contactors –K13/–K14 are de-energized via the position monitoring function of the solenoid. The drives are shutdown in a safety-relevant fashion through two channels via the interlocking circuit, terminals 611–612/613–614. The protective door is initially just released, but is still closed, relay –K17 is energized. Using the PLC, e.g. sub-functions of the user-side machine control, that are still not hazardous, can be executed.

Opening the protective door

By opening the protective door, the protective door safety circuit is opened via the actuator of the door position switch –S11 – redundantly to the position monitoring function of the solenoids.

Closing the protective door

The protective door must be closed. Using pushbutton –S16 – interlock protective door – contactors –K15/–K16 are de-energized (they drop-out) and the protective door is again interlocked. The interlock circuit is again closed through terminals 611–612/613–614 which means in the selected automatic mode, the drives can again be released using pushbutton =4–S32 – start.

For protective doors that are infrequently opened, we recommend that the control is adapted so that each time before the drives are powered up, the position switch function is checked by opening and again closing the door.
8.7.8 Circuit example 7 "Limit switch, limit position monitoring"

**Application/functions**

Normally, the end position (end stop) of the traversing range of the axes in the machine is monitored using software limit switches; these become active after the reference point approach. If, in a fault situation, a software limit switch is passed, and therefore a hardware limit switch actuated, then contactor =4–K21 is de-energized (opened) via the interlocking circuit, terminal 81–82 in the EMERGENCY STOP circuit. The drives are braked at the current limit and are then stopped.

However, electrical braking of an axis is only effective if there is an appropriate distance for the braking travel between the hardware limit switch and the mechanical end stop of the axis.

The actuated end position limit switches can be decoded using PLC inputs. In the setting-up mode, the axis can be moved away in the opposite direction using key-operated switch –S13 and button =5–S11 – "agreement".
8.7.9 Circuit example =8 "Armature short–circuit braking"

Application

Armature short–circuit braking is only possible when using permanent–magnet motors and is used, for example, when passing end position limit switches, when the power fails, for fault signals or EMERGENCY STOP with some delay.

When a software limit switch is passed, the fault/error is often in the NC, PLC or in the drive module itself. Electrical braking beyond the limit position limit switches according to circuit =8 is therefore no longer possible. For critical drives, e.g. vertical axes, in cases such as these, emergency braking is possible using armature short–circuit braking or optionally using a fast shutdown with a holding brake implemented with the appropriate hardware.

The braking torque for armature short–circuit braking is optimized using the additional braking resistor in the motor circuit.

Caution

Short–circuit braking without a braking resistor can result in partial demagnetization of the motor.

Functions

Armature short–circuit

The pulse enable is withdrawn via terminal 663 when the limit position limit switch is actuated/passed or when the power fails. The armature short–circuit contactor –K11 is simultaneously de–energized (opened). The drive is braked after the contactor drop–out time. The interlocking circuit, terminal 91–92, is simultaneously opened therefore initiating an EMERGENCY STOP function for all of the drives. A varistor is connected to the contactor coil in order to achieve a short contactor dropout time. The selected auxiliary contactor from the SIRIUS series of industrial controls with mounted, four–pole auxiliary contact element fulfills “protective separation” between the control voltage and the 690 VAC motor circuit. For operation with power failure and when the +24 V control voltage is buffered, or for other shutdown functions, the circuit must be appropriately adapted to the particular application.

Holding brake

The fast application of the holding brake, independent of the PLC cycle time using the armature short–circuit contactor, supports braking. When compared to armature short–circuit braking, there is a delay before the holding brake actually closes and starts to brake.

In the setting–up mode, the axis can be moved away using the key–operated switch –S13 – move away from end position – and pushbutton =5–S11 – agreement.
8.7.10 Circuit example =9 "Power contactors in the motor circuit"

Application
For special applications, the circuits allow the motor to be galvanically isolated from the drive module via contactors. The contactors may only be de-energized with a leading pulse inhibit >=10 ms via terminal 663 with respect to the power contacts. When powering-up, the pulses must be simultaneously enabled when the power contacts are closed.

Notice
The contactors are generally not suitable for interrupting clocked inverter currents or interrupting DC currents of a stationary drive that is in closed-loop position control. If this is not carefully observed, this can result in high voltage peaks/spikes when powering-down and in turn can destroy the drive module, the motor winding and/or cause the contactor contacts to weld.

Functions
The drives are powered-down in a safety-relevant way using key-operated switch –S11 through one channel or –S15 through two channels – a) using the start inhibit function and b) also using a contactor to galvanically isolate it from the drive module.

The pulse enable is withdrawn before the power contacts of the power contactor open as a result of the drop-out delay. The interlocking circuit, terminals 103–104 or terminals 107–108, should be inserted in the start circuit of the safety combination =4–K31/Y33–Y34, drives stop.
8.8 Information and instructions regarding applications with 611 digital/611 universal

Fig. 8-23 Circuit example, 611 digital with SINUMERIK 840D
8.8.1 Circuit example, 611 digital with SINUMERIK 840D

A circuit example SIMODRIVE 611 digital and SINUMERIK 840D with the drive–related control for a machine/plant, based on the circuit examples in Fig. 8-23 with 611 in its principle form, is shown in Section 8.7.

8.8.2 Circuits with 611 digital

The digital control units 611 digital have a digital setpoint and actual position value interface to the 840D or 810D NC control systems. The boards are available as either 1–axis or 2–axis modules with High Performance or High Standard control.

Further, the units differ in the connection version:

* Incremental encoder as motor encoder (indirect measuring system), or
* Incremental encoder as motor encoder (indirect measuring system) and connection for a direct measuring system encoder

For a description of the interfaces of the 611 digital control units —> refer to Chapter 5.

All of the NC control communications to the 611D drive modules are realized via the digital drive bus. The axis–specific controller and pulse enable signals as well as the operating and monitoring signals are placed on the digital drive bus via NC/PLC interface signals.

The terminal 663 pulse enable/start inhibit for the 611D modules is provided on a module–for–module basis. The axis–specific pulse enable signals received via the drive bus are logically ANDed with the signal state at terminal 663.

Control with SINUMERIK 840D

The NC control with the integrated PLC–CPU SIMATIC S7–300 is accommodated in a 50 mm wide housing that is compatible to the SIMODRIVE drive modules.

The control is integrated in the SIMODRIVE 611D drive group and can be expanded up to 31 axes. It is located between the NE module and the first drive module in the drive group. The power supply for the internal control voltage is derived from the NE module power supply via the equipment bus. The NC ready signal acts on the ready signal terminal 72–74 of the NE module via the equipment bus.
Control with 
SINUMERIK 810D

SINUMERIK 810D is a highly integrated compact control accommodated in a 150 mm wide housing – compatible to the SIMODRIVE modules – with integrated PLC–CPU SIMATIC S7–300 and 611D power and control sections onboard. The control is available in two versions:

- CCU box with three integrated power modules
  - 2 x 6 A/12 A for FD
  - 1 x 18 A/36 A for FD or 1 x 24 A/32 A for MSD
- CCU box with two power modules
  - 2 x 9 A/18 A for FD

The controller can be expanded with axis expansions consisting of up to five (four) axes + one spindle with separately attached power units. The closed–loop controls are already integrated into the CCU modules. Just like the SINUMERIK 840D, the control power supply is taken from the NE module power supply via the equipment bus.

The NC ready signal acts on the ready signal terminal 72–74 of the NE module via the equipment bus. The control has one hardware terminal 663 pulse enable/start inhibit for all axes together. The closed–loop controllers and pulses are enabled on an axis–for–axis basis and are controlled on the digital internal drive bus via NC/PLC interface signals. The safety–relevant drive–related control for a machine/system with SINUMERIK 810D can be engineered on the user–side based on the circuit examples in Section 8.7.

8.8.3 Circuits with 611 universal HRS / HRS2

The SIMODRIVE 611 universal HRS / HRS2 control board is available as either 1–axis or 2–axis module.

The setpoint can either be entered as analog signal or via PROFIBUS.

The interfaces are described in Chapter 4.

Implementation of the safety–relevant, drive–related control for a machine.

The SIMODRIVE 611 universal control board with analog setpoint interface can be used in a comparable fashion to the circuit examples =1 to =9 in Section 8.7.
8.9 Master/slave operation, SIMODRIVE 611

Two SIMODRIVE main spindle drives can be operated, rigidly and mechanically coupled together if the master drive is closed–loop speed controlled and the slave drive is closed–loop torque controlled.

The application of a master/slave function with "SIMODRIVE 611 universal HRS / HRS2" is shown in the following example:

The master specifies the torque setpoint for the slave via an analog output (terminals 75.x/15 or terminals 16.x/15).

![Diagram showing master/slave operation with SIMODRIVE 611 universal HRS / HRS2](image)

**Warning**

If the rigid mechanical coupling is released, then the slave drive must be simultaneously changed–over to "closed–loop speed control" as otherwise inadmissibly high speeds could occur, which could result in malfunctions.

For information and data on the settings and parameterization associated with this master/slave mode as well as additional possibilities regarding axis couplings, refer to:

**Reader’s note**

For information and data on the settings and parameterization associated with this master/slave mode as well as additional possibilities regarding axis couplings, refer to:

TE3: Speed/torque coupling, master–slave

M3: Axis coupling and ESR
8.10 Star–delta mode

Application

SIMODRIVE 611 supports the use of motors that can changeover between star/delta configurations.

At lower speeds, the drive is operated in the star circuit configuration (high torque) and at higher speeds, in the delta circuit configuration (high stall torque). Changeover is also possible during operation.

The speed when changing-over from a star into a delta configuration (star to delta operation) must lie within the stall power range for star operation (refer to the speed–torque diagram for Y/Δ operation).

A star–delta changeover is only permitted below the star field–weakening speed.

\[ M_{\text{stall}} \leq M \leq M_{\text{rated}} \]

\[ n_{\text{ratedY}} \leq n \leq n_{\text{ratedΔ}} \]

Note

If, in the delta mode, a torque lower than \( M_{\text{rated}} \) is taken, an appropriately smaller power module can be selected (as a maximum up to root 3)!

Warning

During the phase when changing-over from Y to Δ operation, no torque may be demanded from the 1PH motor. In this case, a minimum dead time of 0.5 s must be taken into account for contactor changeover times, safety margins, de-magnetizing and magnetizing operations.

The star–delta operation of synchronous motors with 611D modules is used to extend the speed range.

The speed range selection may be changed only in the stopped state.
Danger

If synchronous motors are operated with speeds that require a VPM, the star–delta contactors must be protected using a safe power supply so that in case of fault, this contactor remains reliably switched on until the motor has reached uncritical speeds (EMC voltage)!

This must be proved in a risk evaluation of the machine/plant constructor!

Connection example

Connection diagram for Y/Δ changeover, 1PH Motor with SINUMERIK 840D

Notes:

1) A safe standstill is not guaranteed by just opening K1 and K2.
   This is the reason that for safety–related reasons, contactor $K_x$ should be used to provide electrical isolation. This contactor may only be opened/closed in the no–current condition, i.e. the pulse enable must be withdrawn 40 ms before the contactor is opened (de–energized). Refer to Sections 9.4.2 and 9.7. Circuit example =10.

The connection diagram for Y/Δ changeover 611 universal HRS / HRS2 can be engineered, based on the previous examples. For a description of the function, refer to the separate Configuration Manuals and documentation for SIMODRIVE 611 universal.
### Dimensioning and selecting the contactors

The main contactors must be dimensioned/selected, harmonized and coordinated with the rated motor current and the overload factor.

The following table showing the assignment between 1PM4/6 motor/main contactors and auxiliary contactors can be used to provide configuration support:

#### Table 8-3  Dimensioning and selecting the main contactors for 1PM motors

8.11 Series reactor in the motor lead

General

For special motors with a low leakage inductance (where the controller settings are not adequate) it may be necessary to provide a series reactor as 3–arm iron reactor (not a Corovac reactor) and/or increase the inverter clock cycle frequency of the converter. Motors with a low leakage inductance are, from experience, motors that can achieve high stator frequencies (maximum motor stator frequency > 300 Hz) or motors with a high rated current (rated current > 85 A).

Selection/calculations

- The voltage rate–of–rise (gradient) of the drive converter has typical values such as: 
  \( \frac{du}{dt} \) up to 7 kV/\( \mu \)s

- For third–party motors where the insulation is unknown or not designed for this voltage rate–of–rise, a series reactor should be used, independent of the selected pulse frequency.

- In the IM mode, motors can be used with a maximum rated torque of:
  \[
  M_n = \frac{P_n \cdot 60}{2\pi \cdot n_n} \leq 650 \text{ Nm}
  \]

The inductance value of a series reactor or the necessary drive converter pulse frequency can be estimated using the following formula. However, it must be taken into account that when the inverter clock cycle frequency is increased, the module current must be reduced; or, a module with a higher current rating must be selected:

\[
L_{\text{series}} = \frac{U_{\text{DC link}} \cdot n_{\text{max}}}{30 \cdot f_T \cdot n_{\text{FS}} \cdot I_0} - \frac{L_{\text{L1}} + L_{\text{L2}}}{2}
\]

- \( L_{\text{L1}} \) Stator leakage inductance of the motor in H
- \( L_{\text{L2}} \) Rotor leakage inductance of the motor in H
- \( L_{\text{series}} \) Inductance of the series reactor in H (=0, if a series reactor is not used)\(^1\)
- \( V_{\text{DC link}} \) Voltage
  (=600 V or 625 V for a regulated infeed, = rectified line supply voltage for a non–regulated infeed e.g. 570 V at 400 V_{\text{rms}} line supply voltage)
- \( f_T \) Inverter clock cycle frequency of the converter in Hz, refer to Chapter 5.4.1
- \( n_{\text{max}} \) Max. motor speed
- \( n_{\text{FS}} \) Speed at the start of field weakening
- \( I_0 \) Motor no–load current in A_{\text{rms}}
- \( V_{\text{nmot}} \) Rated motor voltage in V_{\text{rms}}
- \( n_n \) Rated motor speed

\( 1\) For calculated/theoretical inductance values less than 0.1 mH, a series reactor is not required.

For calculated inductance values > 0.4 mH, 0.4 mH must always be assumed as maximum value.
If the motor data are not known, then for motors with a high current (rated current > 85 A), the converter current should be dimensioned for a pulse frequency of 4950 Hz. This means that a drive converter reduction factor of approx. 83% is obtained.

- For motors that require a higher motor frequency than 500 Hz, the drive converter pulse frequency must be increased.

The following formula applies:

\[
 f_T \geq 6 \cdot \frac{f_{\text{max mot}}}{f_{\text{T}}} \]

- Inverter clock cycle frequency of the drive converter in Hz, refer to Chapter 5.4.1
- Max. motor stator frequency

It should be noted that for inverter clock cycle frequencies above 3200 Hz, the module current rating must be reduced or, if required, a module with a higher-current rating must be selected.

- The max. field-weakening range for induction motor operation is limited.

The following relationships apply:

\[
 \frac{n_{\text{max}}}{n_{\text{FS}}} \leq \begin{cases} 
 2 & \text{for high-speed motors (max. output frequency > 300 Hz),} \\
 5 & \text{Standard motors} \\
 5 & \text{for wide-range motors} \\
 \end{cases} 
\]

- Max. motor speed
- Speed at the start of field weakening for the motor

An approximate value can be calculated with:

\[
 n_{\text{FS}} = \frac{U_{\text{DC ink}} \cdot n_n}{1.6 \cdot V_{\text{nmot}}} \]

(refer above)

If a motor is changed-over from delta to star operation and vice versa, and auxiliary and main contactors are required for each motor. The motor contactors must be mutually interlocked. The changeover is only made when the pulses are inhibited using select terminal signals. When the changeover command is issued, the motor data set is reloaded and the auxiliary contactors are controlled via the selector relay.

Parallel operation of several induction motors, refer to Chapter 8.12.1.

- The voltage drop across a series reactor depends on the motor current and the motor frequency. If an unregulated infeed is used, the maximum rated motor voltage depends on the line supply voltage available.

If these guide values are not observed, then this can have a negative impact on the power (lower power) in the upper speed range.
8.12 Induction motor operation

8.12.1 Operating several induction motors in parallel

Several motors can also be operated in parallel on a power module, for each axis. When selecting the motor and drive module, several engineering guidelines must be observed.

When expanded to the maximum, a drive configuration for parallel operation can comprise up to eight motors. Motors connected to a drive module in parallel must have the same V/f characteristics. Further, we recommend that the motors have the same number of poles. If more than two motors are connected to a drive module, then these should essentially have the same power ratings.

For a 2–motor configuration, the difference between the power ratings of the motors should not exceed a ratio of 1:10.

The following engineering guidelines must be carefully observed:

- Selecting the size of the drive module
  - Steady–state operation of the motors connected in parallel – namely in the closed–loop controlled range (> \( n_{\text{min}} \)) and preferably in the rated speed range:
    \[ \sum \text{rated motor currents} \leq \text{rated current of the drive module} \]
  - Operation of motors connected in parallel with dynamic load (where the load condition changes quickly) and in the open–loop controlled range require an additional dimensioning:
    \[ 1.2 \left( \sum \text{rated motor currents} \right) \leq \text{rated current of the drive module} \]
  - The current limit of the drive module must be increased to 150% of the rated current when commissioning the system.

- The motors should not be subject to torques that exceed their rated torque.

- For special high–speed induction motors, e.g. for woodworking, a series reactor must always be located between the drive module and the motor group:
  
  \[ \text{Rated reactor current: rms current of the motor group} \]

When the above information and instructions are taken into consideration, the individual motors are able to correct even for dynamic load and speed steps. "Stable" operation without stalling – also for individual motors – is achieved when following the dimensioning guidelines specified above. The speeds of the individual motors depend on the load. The currently set speeds can drift apart by several percent due to the closed–loop group slip control.

---

1) Standard motor: 2-pin→ > 600 RPM
   4-pin→ > 300 RPM
   6-pin→ > 200 RPM
   8-pin→ > 150 RPM

Special motors: \( n_{\text{min}} > \frac{40 \text{ V} \times n_{\text{rated}}}{U_{\text{rated motor}}} > \frac{600 \text{ RPM}}{\text{No. of pole pairs}} \)

2) \( \sum \) Rated motor currents, or when taking into account the load duty cycles, the total rms current of the motor group.
Load surges and overload conditions in the field–weakening range can result in oscillation and should be avoided.

The drive module cannot detect if an individual motor is overloaded.

Individual thermal monitoring functions must be provided to ensure that each individual motor has overload protection. We recommend that the motor is monitored using a PTC thermistor evaluation circuit.

**Notes:**

1) $\Sigma$ Rated motor currents, or when taking into account the load duty cycles, the total rms current of the motor group

---

*Notice*

For parallel operation, all of the motors must always be operated simultaneously. The motor data set must be adapted, e.g. by using a motor changeover function, when a motor is shutdown, e.g. when a fault condition develops.

When motors are connected in parallel, motor cable protection must be implemented outside the drive converter.
8.12 Induction motor operation

8.12.2 Selecting individual induction motors 611

The "SIMODRIVE 611 universal HRS / HRS2" drive allows up to four different motors to be selected. Every motor has its own motor parameter set.

Notes:
1) Several motors cannot be simultaneously selected as this is interlocked per software. The recommended contactor interlocking additionally guarantees that only one motor can be operated at any one time.
2) This is only required for special high speed motors.

Fig. 8-28 Motor changeover at SIMODRIVE 611 universal HRS / HRS2

For the motor selection circuit, one 3RH11 auxiliary contactor and one 3RT10 main contactor are required for each motor.

Reader’s note
For additional information and possibilities for selecting and changing–over induction motors, refer to:

References: /FBU/ SIMODRIVE 611 universal, Description of Functions
8 Important Circuit Information

8.12 Induction motor operation

Overload protection

Individual thermal monitoring functions must be provided for overload protection of the individual induction motors. We recommend that the motor is monitored using a PTC thermistor temperature sensor (embedded in the motor) and a 3RN1 thermistor motor protection evaluation unit.

If motor feeder cables have to be protected where the rated drive converter current is significantly greater than the rated motor current then this must be implemented outside the drive converter.

Notice

Motors may only be changed over using the power contactors in the motor circuit when terminal 663 – pulse enable/start inhibit – is inhibited (de-energized). This means that the power contactor may only be switched when the motor circuit is in a no-current condition.

For additional information also refer to circuit examples =9 in Section 9.7
8.13 Operation when the power fails

8.13.1 Application and mode of operation

The function "operation with the power fails" (power failure buffering) is used, for example, for machines where personnel could be in danger or significant machine damage could occur due to a danger of collision when machining due to power failure or for internal control fault signals. Further, the function is used for machines with complex machining operations. For example, when machining gear wheels (hobbing, roller grinding) where expensive tools and workpieces are used and which should be protected from possible damage if power failures were to occur.

For operation when the power fails, stopping and/or retracting drive motion, the energy stored in the capacitors of the power DC link and the kinetic energy of the moved masses stored when the drives regenerate into the line supply can be briefly used. To do this, a connection must be established from the power DC link P600/M600 to the auxiliary power supply via the terminals P500/M500 in the NE module or in the monitoring module.

Further, additional circuit measures are required. For example, the control voltages must be buffered and a power failure and/or DC link monitoring function to initiate the appropriate control functions.

After a hazard analysis, the machinery construction OEM must evaluate these risks and requirements and apply appropriate measures to avoid such hazards or damage.

The requirements placed on the power failure concepts differ significantly depending on the user and machine and must therefore be individually engineered.

8.13.2 Functions

An essential criterion when implementing power failure concepts is to be able to quickly detect a line supply fault (power failure, line supply undervoltage or phase failure).

When a line supply fault occurs, the DC link voltage quickly dips/fails due to the power drawn by the drives and the connected power supplies for the drive and control components. The discharge time depends on the DC link capacity, the charge (voltage) and the loading after the power failure.

Operation when the power fails with initiation of the regenerative feedback of one or more drives into the DC link must become effective before the DC link voltage decreases below the rated voltage, e.g. 600 V DC to 350 V DC. At approx. 350 V, the pulses are internally inhibited in the drive group, and the drives coast down.

The DC link voltage of 600 V DC is proportionally emulated at the control level and can be evaluated in the 611 digital and 611 universal control units via the equipment bus. The DC link voltage can be monitored to provide a fast response using parameterizable limit value stages, e.g. to 450 – 500 V. This therefore allows indirectly, an immediate response to be made to a line supply fault, e.g. power failure.
The ready signal via terminals 72–74 in the NE module also responds when a line supply fault occurs and inhibits the pulses in the NE module. The response time is, among other things, dependent on the line supply impedances and other quantities and can therefore not be precisely calculated in advance. Generally, the power failure detection time is >30 ms and is alone not sufficient to initiate functions for operation when the power fails (line supply failure).

**Operation when the power fails with the SIMODRIVE 611 universal HRS / HRS2**

Example:
The DC link voltage is monitored using the limit value stage of a 611 universal HRS / HRS2 control board in the SIMODRIVE 611 universal HRS / HRS2. When a selectable limit value is undershot, e.g. a DC link voltage of 550 V, the limit value stage responds and switches a positive output signal from +24 V to 0 V via a digital output stage. For example, terminal 64 – drive enable – can be inhibited in an “AND” logic operation with the relay contact of the ready signal of terminals 72–73.1 of the NE module. The drives are braked and stopped as quickly as possible at the current limit.

In addition, for example, via a second digital output of the 611 universal module, the setpoint polarity of a drive can be changed-over and retraction motion initiated for a drive before the other remaining drives are braked, delayed via terminal 64.

The safety–relevant circuit examples in Section 8.7 for the drive control must be appropriately adapted by the user for operation when the power fails (line supply fault).

Additional possibilities for braking when the power fails:
Braking using armature short–circuit braking for permanent–magnet servomotors, refer to circuit example =8 in Section 8.7.

**Note**
The power failure monitoring device must directly interrupt the coil circuit of the armature short–circuit contactor as a buffered +24 V power supply will either respond too late or not even respond at all.

Braking by quickly applying the holding brake, bypassing the PLC cycle time, refer to circuit example =8 in Section 8.7.

**Note**
The holding brake is not an operating brake and can only be conditionally used for such braking operations.
Operation when the power fails with SIMODRIVE 611 digital in conjunction with SINUMERIK 840D

Extended stopping and retraction: ESR

These more complex functions can be used in conjunction with the optional software NC functions that can be used in SINUMERIK 840D and the digital drives 611D with High Performance controls.

For certain machining technologies where several drives, for example, interpolate with one another using electronic gear functions, when the power fails, these drives must be stopped or retracted in a coordinated fashion using special NC functions.

The user must engineer these functions for the special requirements of the particular machining process or technology.

Also here, the DC link voltage is monitored for a lower threshold value that can be parameterized. When a limit value, selected using a machine data is fallen below, within just a few interpolation clock cycles, the NC quickly responds via the digital drive bus and stops the drives in a controlled fashion and/or raises, retracts the tool from the machining contour.

Further, for example, when a connection between the NC and the drives is interrupted, for a sign–of–life failure of the NC or other selected fault signals in the drive system, the drives can be stopped/retracted using a drive–based function, i.e. a function that runs autonomously in the drives.

When the power fails, the energy required to stop/retract the drives is supplied from the energy stored in the capacitors of the power DC link.

If the energy is not sufficient, the DC link capacitance can be increased by adding additional capacitor modules, refer to Chapter 6. However, the charging limit of the I/R module must not exceeded.

However, for cases where the energy stored in the DC link is still not sufficient to stop/retract the drives, an additional energy storage device can be activated through regenerative operation. As an autonomous drive mode when line supply faults occur, it provides the necessary energy for the drive DC link.

A detailed description of “Extended stopping and retraction” –ESR– is contained in the following reference:

References: /FB3/ SINUMERIK 840D/840Di/810D Special Functions Part 3 “Axis couplings and ESR”.

Dynamic energy management enables I/RF unit dimensioning to be adapted to the plant concept in accordance with requirements.

A detailed description of “Dynamic Energy Management” is contained in the following reference:

8.13 Operation when the power fails

The following control and secondary conditions/limitations must be carefully taken into consideration when engineering and configuring power failure concepts:

- The braking energy must be converted into heat using one or more pulsed resistor module(s) – or for unregulated infeed units, using the internal pulsed resistor (it may be necessary to use, in addition, an external resistor). When the drives brake, the DC link voltage may not fall below or exceed the max. set monitoring thresholds.

- The safety-relevant hardware control must, when the power fails, e.g. briefly maintain the enable signals via terminals 48, 63, 64, NS1, NS2 and 663. Further, the internal axis-specific enable signals of the NC/PLC interface via the digital drive bus must also be maintained until the drives come to a standstill.

- For controlled retraction motion, holding brakes must remain energized, if required, until the operation has been completed and clamping operations must be released.

- The external +24 V power supply for the control voltage must be buffered using power supply units, e.g. SITOP power with capacitor or battery back-up. This maintains the drive enable signals, the PLC functions, and the control and machine functions on the user side.

- During the braking and retraction phase, it is not permissible that the NC and PLC controls generate fault signals that inhibit the drives.

- The power supply of the SINUMERIK 840 D with the integrated PLC-CPU is supplied through the DC link of the NE module when the power fails.

8.13.3 DC link buffering

The energy stored in the DC link of the drive units can be used when the power fails. Capacitor modules are used to increase the DC link capacitance. This means that on one hand, a brief power failure can be buffered and on the other hand, it is also possible to store the braking energy.

Note

Examples to calculate and select a capacitor module, refer to Chapter 6.7.1.

Energy balance

When configuring the emergency retraction, it is always necessary to consider the energy flow (balance) to find out whether you can do without an additional capacitor module or a generator axis/spindle (with correspondingly dimensioned flywheel effect).
8.14 SINUMERIK Safety Integrated

General information

"SINUMERIK Safety Integrated" offers type–tested safety functions which allow highly effective personnel and machine protection to be implemented in–line with that required in practice.

All safety functions satisfy the requirements specified in 954–1, Category 3, Performance Level d in accordance with EN ISO 13849–1, SIL 2 in accordance with EN 61508 and are a standard part of the base system.

Neither additional sensors nor evaluation units are required; this means lower installation time and costs at the machine and a "low profile" electrical cabinet.

The function scope includes, e.g.:

- Safety–relevant monitoring of velocity and standstill (zero speed)
- Safety–relevant traversing range demarcation and range identification/detection

Reference

Please refer to the following documentation for a detailed description of SINUMERIK Safety Integrated:

Reader’s note

References:
/FBSI/ Description of Functions, SINUMERIK Safety Integrated
/HBSI/ Application Manual, Safety Integrated

Direct connection of two–channel I/O signals

Using the additional, integrated functions in the safety package "Safety Integrated" for SINUMERIK 840D/611D, for the first time, it is also possible to directly connect two–channel I/O signals – for example, an Emergency Stop button or light barriers. Logic operations and responses are performed internally using safety–related technology.

Mastering extreme conditions professionally

All safety–relevant faults/errors in the system always cause potentially hazardous movement to be brought to a standstill or the motor to be contactlessly disconnected from the line supply. The drives are brought to a standstill in the optimum way, adapted to the operating conditions of the machine. This means, for example, in the setting–up mode with the protective door opened it is possible to stop axes as quickly as possible path–related – and also in the automatic mode with closed protective door.

This means: High degree of protection for personnel in the setting–up mode and additional protection for the machine, tool and workpiece in the automatic mode.

Highly effective safety concept

The safety functions provide a previously unknown, intelligent and direct link right through the system to the electric drives and measuring system. Reliable operation, fast response and wide acceptance mean that this certified safety concept is extremely effective.

Safety functions incorporated redundantly

A two–channel, diverse system structure has been formed on the basis of the existing multi–processor structure. The safety functions have been configured redundantly in the NC, drive and internal PLC. A feature of this safety concept is that a measuring system, the standard motor measuring system, can already satisfy the safety requirements. A second sensor is not necessary but can be added as an additional, direct measuring system, e.g. linear scale.

Innovative safety technology setting new standards

It has been clearly seen that new practical machine operation concepts can be implemented with this innovative safety technology. The result is a new standard for machines which makes them safer and more flexible to use and which increases the availability of the entire plant.
8.15 Examples of correctly and incorrectly connecting NE to the line supply

8.15.1 Three–conductor connection to the line supply

Note
- All X181 connections of a drive group must be electrically switched in parallel!
- A maximum of four monitoring modules may be connected at X181 of an NE module.
- If a DC link is buffered (DC link connection), the voltage must always be taken from between the reactor (Lk) and the line supply infeed (NE).
- For all of the following examples, cables must be routed so that they are short-circuit and ground-fault proof (or fuse)!

Consequences when incorrectly connected to the line supply:
1) Arcing with respect to PE in the power supply
   Refer to the use of HF/HFD commutating reactor to prevent system oscillations in Chapter 6.5.
   Consequences when the system oscillates: Burned overvoltage limiting module

2)/3)/4):
   • More than four monitoring modules:
   • Additional loads:
   Consequence: Burnt PC board tracks on the line infeed module (NE module) power supply

Fig. 8-38 Additional examples for frequent faults/mistakes when connecting to the line supply
8.16 VPM Voltage Protection Module

8.16.1 General information

The Voltage Protection Module VPM (voltage limiting module) is used for permanent-magnet synchronous motors with an EMF of 800 Vrms up to 2000 Vrms in order to limit the DC link voltage at the converter in the case of a fault. The Voltage Protection Module is connected between the power module and motor in the motor cable. If, at maximum speed, the line voltage fails, or if as a consequence of this, the converter pulses are deleted, the synchronous motor feeds back the full voltage into the DC link.

The VPM identifies an excessively high DC link voltage (> 800 V) and short-circuits the three motor feeder cables. The energy remaining in the motor is converted into heat as a result of the short-circuit between the VPM and the motor feeder cables.

The Voltage Protection Module is available in 3 different versions.

When using third-party synchronous motors (generally, with higher inductances then 1FE motors), when combining a third-party synchronous motor with a series reactor as well as the combination of 1FE motor with series reactor, then the VPM 200 Dynamik should be used.

The reason for this is the higher operational inductances and as a consequence, higher voltage rates rise, which can effect of the VPM.

8.16.2 Integration

It must be installed according to the connection schematic VPM 120 (Fig. 8-42) or VPM 200/200 Dynamic (Fig. 8-43).

Series reactors may only be connected between the VPM and motor.

Clearances of approx. 200 mm must be provided above and below the unit for cable entry.

It can be mounted in any position.

It is not permissible that switching elements are inserted in the connecting cables U, V, W between the drive, VPM and motor!

The air intake temperature, measured 10 mm below the unit, may not exceed 55 °C.

Caution

After switching off all of the voltages, hazardous voltages are present for up to 4 minutes (capacitance of the 611 converter capacitor). The voltage must be measured to ensure that there are no hazardous voltages present!

Notice

The unit is a safety–relevant piece of equipment and may only be used as specified. Other application, e.g. armature short–circuit in operation and others are not permissible.

The warning information on the unit must be carefully observed!

Operation with VPM is only permitted in conjunction with the SIMODRIVE 611 digital, SIMODRIVE 611 universal, converter system, shielded Motion-Connect 800 motor supply cables, and enabled permanent–magnet induction motors.

Warning

Motors with an EMF that can achieve a DC link voltage > 2 kV (EMF = 1.4 kV eff) at the highest speed are not permitted to be connected to the SIMODRIVE 611. In this case, the insulating voltage could be exceeded, resulting in personal injury due to electric shock.

Voltages \( U \leq 2 \text{kV} \) can occur at cables/conductors that are cut or damaged.

In the event of an error, the terminal voltage of the permanent–magnet induction motors can assume values \( U \leq 2 \text{kV} \).

Hazardous voltage is still present approximately 4 minutes after all voltages have been shut down (capacitor capacity of the SIMODRIVE 611 converter). In order to ensure that no hazardous voltages are present, the voltage must first be measured.
Die folgenden Zeichnungen zeigen die prinzipielle Lage der Schnittstellen und der Gehäusedurchlässe der Voltage Protection Modules VPM 120, VPM 200 und VPM 200 Dynamik.

Fig. 8-39  Voltage Protection Modules VPM 120 (without cover)
In operation, the housing is closed so that the electrical connection points are covered.
For the power connections to the power module and for the motor, the cables are routed through the cable glands of the Voltage Protection Module and connected to the connecting bars inside the device.

**Fig. 8-42 Connection, VPM 120**
Connection VPM 200/VPM 200 Dynamik

For the power connections to the power module and for the motor, the cables are routed through the cable glands of the Voltage Protection Module and connected to the connecting bars inside the device.

- Wiring diagram

Fig. 8-43 Connection VPM 200/VPM 200 Dynamik
### 8.16 VPM Voltage Protection Module

- **Connection of internal cable routing and VPM 200 Dynamik**

**Wiring sequence**

- Attaching the four cable glands
- Strip cable to approx. 300 mm, based on the cable glands you are using, and expose the shield connection
- Apply the cable lug
- Connect the cables to X3 and secure them with the cable tie (see Fig. 8-46)
- Insert K1 and K2 into VS1 and VS2 and pull taught, making sure that the black cable (L1) and the protective cable are on top.
- Connect the individual cables in the following order:
  - K1 blue (L2) ⇒ V1
  - K2 blue (L2) ⇒ V1
  - K2 green/yellow (PE) ⇒ PE1
  - K1 brown (L3) ⇒ W2
  - K2 black (L1) ⇒ U2
  - For the time being, do not connect the remaining three cables
- Insert K3 and K4 into VS3 and VS4 and pull tight, making sure that the black cable (L1) and the protective cable are on top.
- Connect the individual cables in the following order:
  - K3 blue (L2) ⇒ V2
  - K4 blue (L2) ⇒ V2
  - K3 brown (L3) ⇒ W3
  - K4 green/yellow (PE) ⇒ PE4
  - K4 black (L1) ⇒ U4
  - K3 black (L1) ⇒ U3
  - K2 brown (L3) ⇒ W4
  - K4 brown (L3) ⇒ W1
  - K3 green/yellow (PE) ⇒ PE3
  - K1 green/yellow (PE) ⇒ PE2

Where:
- K1: Cable 1 (from the converter)
- K2: Cable 2 (from the converter)
- K3: Cable 3 (from the motor)
- K4: Cable 4 (from the motor)
- VS1 to VS4: Cable glands 1 to 4
- U1 to U4: Terminal studs 1 to 4, phase U
- V1 and V2: Terminal studs 1 and 2, phase V
- W1 to W4: Terminal studs 1 to 4, phase W
- PE1 to PE4: Terminal studs 1 to 4, busbar PE
- U: Busbar, phase U
- V: Busbar, phase V
- W: Busbar, phase W
- PE: Busbar PE

---

**Fig. 8-44 Connection of internal cable routing and VPM 200 Dynamik**
Signal contact X3

When the VPM is tripped or in the event of a temperature fault, signaling contact X3 opens and interrupts the pulse enable of the SIMODRIVE converter (see Fig. 8-45).

Warning

The signaling contact X3 closes autonomously after t > 2 min or after the temperature switch has been reset. Therefore, measures must be adopted to prevent the drive from starting by itself!

Fig. 8-45  Signaling contact X3 of the VPM

Note: This value is valid 15 s after the drive and pulse enable

Terminal type: Spring loaded terminal WAGO, type 226–111, cable cross-section max.: 1,5 mm², shielded cable

Cable gland: max. 9 mm ∅.

Types VPM 120, VPM 200 and VPM 200 Dynamik

- Screwed connection: 1 x M16, z. B. Fa. Pflitsch, Order No.: UNI DICHT EMV 2165211S05
- Counter nut: M16: GM216PA.

Caution

When a VPM is tripped, the short-circuit thyristor must be safely cleared before the connected drive can be switched on again. This is only ensured if the motor has first come to a standstill.

An X3 signal contact that has closed again is **not an explicit indication** that this has occurred.

Be especially cautious of this in the event of servicing.
8 Important Circuit Information

8.16 VPM Voltage Protection Module

**Note**

Signal contact X3 of the VPM is routed via a bistable relay. Very significant shocks that occur during transport and installation can cause the relay to go into the other switching state. As a consequence, it cannot be guaranteed that the system will start.

To resolve the fault:
1. Connect terminal 9 and terminal 663 (pulse enable)
2. Switch–on SIMODRIVE 611D
3. Allow the spindle to rotate at an average speed for at least 2 seconds
4. Switch–off SIMODRIVE 611D; the relay is reset when the internal 24 V supply is switched off
5. Remove the jumper between terminal 9 and terminal 663

**Cable lengths**

The maximum length of the power cable between the power module and Voltage Protection Module is 1.5 m. It is not permissible that this module includes any switching elements.

The power cable between the Voltage Protection Module and the motor must not exceed a length of 50 m.

The maximum length of the signal cable is 10 m.
Connecting the X3 signaling contact

To check the function of the VPM, operate the motor at a speed for which the EMC of the motor would be approx. 650 V eff. An oscilloscope is used to measure the motor voltage. This requires that a pulse inhibit is initiated on the converter system and on the I/R unit. When the VPM is activated, the motor voltage must fall to just a few volts, if not, the VPM is defect!

Note

To measure the EMC:

Perform the measurement with the oscilloscope. For the measurement, either potential-separate active voltage dividers for high voltages or passive probes explicitly suitable for voltages above 1.5 kV must be used. Multimeters, also not effective value multimeters, cannot be used.

No standard probes may be used for the oscilloscope measurement. For measurement with passive probe, the ground clip must be set to ground, under no circumstances to the converter terminal. Then use the oscilloscope to subtract two channels, e.g. U voltage to ground and V voltage to ground, from each other and display the result on the screen.
8.16.3 Mounting

The Voltage Protection Module is mounted in the cabinet close to the drive.

**Danger**

It is only permissible to connect motor reactors between the Voltage Protection Module and the motor.

---

9.1 Installation and connecting–up regulations

Note

The "SINUMERIK, SIROTEC, SIMODRIVE, SINAMICS S120 EMC Directive" (Order No.: 6FC5297–0AD30–0AP□) must always be observed; refer to the documentation overview on the cover page.

Chapter 9 contains only product–specific additions!

Caution

Carefully ensure that the line filter is connected to the line supply in–line with the specifications/regulations:

LINE L1, L2, L3 for line filters for the UI module and I/R module for sinusoidal current mode.

If this is not observed, the line filter could be damaged. Also refer to the connection diagram 9-1.

Caution

The line filters listed conduct a high leakage current over the PE conductor. A permanent PE connection for the filter or control cabinet is required due to the high leakage current of the line filters.

Measures according to EN 50178/94 Part 5.3.2.1 must be taken, e.g. a PE conductor (>10 mm² Cu) or a second conductor must be routed electrically parallel to the PE conductor via separate terminals. This conductor must also fully meet the requirements for PE conductors according to IEC 60364–5–543.

Applications

The line filters described have been dimensioned to suppress SIMODRIVE 611 drive converters; they have not been designed to suppress (noise/interference suppression) other loads in the electrical cabinet. A dedicated filter must be provided for other loads in the electrical cabinet.

If the electronics power supply is connected to a separate line supply, then the feeder cable must be routed through a second filter. The feeder cable to the electronics power supply (connector X181) must be shielded and the shield must be connected at both ends at the connector side as close as possible to connector X181 – on the cabinet mounting panel.

The line supply connection for fan units must also be routed through a second filter.
9 Cabinet Design and EMC

9.1 Installation and connecting-up regulations

Mounting in the electrical cabinet

The line filter must be located in the same cabinet field close to the NE modules; the cable (shielded above 1 m) connecting the line filter to the NE module should be kept as short as possible. The incoming and outgoing cables to/from the line filter must be routed separately from one another.

Recommended configuration, refer to Fig. 9-1.

Note

If the system is subject to a high-voltage test using AC voltage, a line filter must be disconnected in order to obtain a correct measurement result.

Connection cable shield

A permanent strain relief for the cables must be present. These cables must not pass strain forces to the cable shielding!

Shield connecting plates with a clamp connection are provided on the NE and PM modules to connect the shields of shielded powered cables; mounting locations are also provided for brake terminals (Order No., refer to Table 9-1. Also refer to the dimension drawing “EMC measures”, Chapter 12).

Table 9-1 Order Nos. for the shield connecting plates

<table>

</tbody>
</table>

If the motor is equipped with a brake, then the shield of the brake feeder cable must be connected at both ends to the shield of the power cable.

If there is no possibility of connecting a shield on the motor side, a gland must be incorporated in the terminal box with the possibility of establishing a shield–motor connection through the largest possible surface area.

Warning

Cable shields and cores/conductors of power cables which are not used, e.g. brake conductors, must be connected to PE potential in order to discharge charges arising from capacitive coupling.

Non-observance can cause lethal shock voltages.
Cables longer than 1 m must be shielded. If unshielded connections are used, an adequate separation > 20 cm must be observed for cables subject to coupling.

1) Shield connection through the largest possible surface area to the cabinet mounting panel.
2) Shield connection at the module–specific connecting plate.
3) PE cables can be, alternatively, connected using a PE rail also observing EN50178 (protective connections).
4) Permissible commutating reactors for I/R module, sinusoidal operation – refer to Sections 3.4.2 and 3.1
   Permissible commutating reactor for 28 kW UI module, refer to Section 3.4.2
   When routing cables into the cabinet, a clearance of > 100 mm must be maintained around the HFD reactor or measures must be taken to discharge the heat/appropriately guide the air.

**Note:**
The filter may only be mounted with the line supply connection at the bottom (downwards).

---

**Note**

1. The EMC measures described above ensure CE compliance with the EMC Directive.
2. Alternative measures can be applied, e.g. routing behind mounting plates, suitable clearances, under the assumption that they have similar results.
3. This excludes measures that relate to the design, installation, and routing of motor power cables and signal cables.
9.1 Installation and connecting–up regulations

9.1.1 Shielded connecting plates

Shield connecting plates are available that can be retrofitted for the infeed and power modules. These plates also have mounting points for brake connecting terminals.

The shield plates should be mounted after the devices have been mounted/installed in the electrical cabinet.

The screw(s) 1 below should be loosened so that the keyhole can be engaged in the shield plate, and then mounting is continued in the sequence 2, 3, 4.

When removing the module, proceed in the inverse sequence.

![Fig. 9-2 Mounting the shielding plate](image)

Shield connection cables

The shield connection is used to ensure that cables for electronics, e.g. incremental shaft–angle encoders for SIMODRIVE 611 universal HRS / HRS2, are connected to the ground potential of the module housing in compliance with EMC (for Siemens encoder cables, the shield is connected in the encoder connector). The shield connection is mounted above the control units using the screws supplied above the threaded sockets at the power modules.

Order No. (MLFB): 6SN1162–0FA00–0AA

Note

For SIMODRIVE 611, the 6SN1162–0FA00–0AA2 shield connection can be used for in–house assembled sensor lines, e.g. for TTL encoder to SIMODRIVE 611 universal.
9.1 Installation and connecting–up regulations

The shields of original pre–assembled cables are automatically connected when the cable is plugged–in.

Exceptions:

- Setpoint cable from the analog NC
  Here, the shields of the setpoint pairs must be connected to the upper side of the module. The threaded sockets provided can be used for this purpose (M5x10/3 Nm).

- Drive bus cable from SINUMERIK 840C
  Here, the shield is connected to the threaded socket mentioned above using the clamp provided.

- Drive bus and equipment bus extension cables for 2–tier configurations.
  Here, shields are connected at both ends of the cables to the above mentioned threaded sockets using the clamps provided.

- Motor power cables
  The shields of the motor feeder cables are connected, using the hose connectors provided, to the shield connecting plates (accessories) of the modules.

**Shield connection front panel**

In order to ensure a good connection between the front panel and the housing, the screws at the front panel must be tightened with a torque of 0.8 Nm.
9 Cabinet Design and EMC

9.1 Installation and connecting-up regulations

| Connection, electronics ground | Terminal X131 (electronics ground) at the NC. |
| Protection against overvoltages | In order to provide protection against overvoltage (for line supplies that are not in compliance with VDE), an overvoltage limiter module (Order No.: 6SN1111–0AB00–0AA0) can be inserted at connector X181 on the NE module (this is not necessary for UI 5 kW and monitoring module). |
| Maximum cable lengths | Using non–shielded signal and direct current supply cables (e.g. 24 V infeed with external supply): |
| | • DC power supply cables: Length ≤ 9.90 m permissible. |
| | • Non–shielded signal cables: Length, max. 30 m permissible without any additional circuitry |
| | For longer lengths, the user must connect suitable circuitry to provide overvoltage protection, e.g. the following type: TERMITRAB–UK5/ 24DC |
| | Article no. 27 94 69 9 from Fa. Phoenix Contact GmbH & Co |
| | 32823 Blomberg, Germany |
| | Tel. +49 (0)5235/300 |
| | Fax +49 (0)5235/341200 |
| | http://www.phoenixcontact.com |

Note

We recommend that prefabricated cables are used, as correct shielding is necessary to ensure an EMC–safe connection.

Further, the appropriate cable parameters are required in order to ensure optimum signal transfer characteristics. The function will only be guaranteed when using the original cables.

Reference: /EMC/ EMC Configuring Guidelines SINUMERIK, SIROTEC, SIMODRIVE
9.1.2 Mounting conditions, internal cooling

**Note**
The regulations described in the "SINAMICS S120 Booksize / SIMODRIVE System Manual" switchgear cabinet integration system manual Order No.: 6SL3097–0AT00–0AP□ must be observed for the heat dissipation!

**General information**
If the guidelines for installing/mounting SIMODRIVE 611 equipment in the cabinet are not carefully observed, this can significantly reduce the service life of the equipment and result in premature component failure.

The following specifications must be carefully observed when mounting/installing a SIMODRIVE 611 drive group:
- Cooling clearance
- Cable routing
- Air flow, climate–control equipment

**Cooling clearance**
Minimum 100 mm clearance at the top and bottom for cooling.

![Cooling clearance diagram](image)

Air intake temperature, max 40 °C, at higher temperatures (max 55 °C), the power must be reduced (derating).
Notice

For modules that generate a significant amount of heat, pulsed resistor module, 5 kW and 10 kW UI module, a heat deflecting plate (100 mm wide) should be used to protect the cable from excessive temperature. (For the pulsed resistor module, 50 mm wide, mounted so that they overlap.)
9.1 Installation and connecting-up regulations

Air intake when arranging power modules

Measures are shown in the following diagram if the following conditions/arrangements simultaneously exist in the cabinet:

- Number of power modules (50 mm wide) \( N > 10 \)
- Shield plate
- Channel cable

![Diagram showing air intake measures](image)

The following measures must be applied as a minimum in order to ensure adequate air intake:

- **A**
- **B**
- **C**

Fig. 9-6  Measures when building the cabinet

Cable routing

Cables may not be routed over modules; the ventilation grilles may not be covered. The 50 mm wide devices are especially critical.
9.1.3 Two-tier equipment configuration

**Arrangement**

The modules of the SIMODRIVE 611 drive converter system can also be arranged in two tiers, one above the other or next to each other.

The distance between the rows of modules may not be less than 200 mm to ensure unrestricted cooling. In this case it must be ensured that the cooling air for the upper lineup does not exceed 40 °C – or with derating does not reach 55 °C. Otherwise, measures must be taken, for example an air baffle plate must be used or offset mounting, see Fig 9-8. As a result of the equipment bus cable, dependent on the design, the maximum clearance is specified.

When arranging the cable ducts that may be required for the wiring it must be ensured that the required minimum clearance to the SIMODRIVE 611 converter system is not fallen below.

The modules with the higher power ratings – as well as the infeed module – must be located in the upper row of modules.

The maximum expansion phase of a drive group is limited by the power rating of the infeed module. Only one equipment bus extension is permissible: Either to the left, e.g. for a second tier; or to the right, e.g. to bypass a cubicle panel.

**Connecting cable**

For the SIMODRIVE 611 drive converter system, for a two-tier equipment configuration, a connecting cable is required for the equipment and drive bus.

In the two-tier equipment configuration, the DC link is connected using parallel cables (max. length, 5 m; in conjunction with SIMODRIVE POSMO SI/CD/CA, the guidelines correspond to the User Manual SIMODRIVE POSMO SI/CD/CA).

The required cable cross-section of the connecting cable for the downstream modules can be obtained from the dimension drawing in Fig. 12-60. The three cables should be tied together. These cables are not included with the equipment.

The dimensions, specified in the diagram 9-7 apply for the DC link connection of components that are separately located next to each other, e.g. extending over several electrical cabinets.

**Adapter terminals to connect the DC link**

Adapter terminals are available to connect the DC link.

The DC link voltage can be connected further using these adapter terminals, e.g. to connect the DC link for two-tier configurations.

The following adapter terminals are available (refer to Fig. 9-7):

- Package with two double terminals 50 mm² for a module width 50...200 mm (to 100 A also for a module width of 300 mm) (Order No.: 6SN1161–1AA01–0BA0)
- Package with two double terminals 95 mm² for a module width of 300 mm (Order No.: 6SN1161–1AA01–0AA0)

**Danger**

Notice! Order No.: 6SN1161–1AA01–0AA0 Do not use for module widths 50 – 200 mm. Danger of death because the contact safety is endangered!
9.1 Installation and connecting-up regulations

For the NC control system

Equipment bus cable

Connection: short-circuit resistant, cable/busbar

Terminating connector for the drive bus

Round cable

Adapter terminals, Order No.
For module width, 50 – 200 mm
6SN1161–1AA01–0BA0
For module width, 300 mm
6SN1161–1AA01–0AA0

2) Danger notice!
Do not use for module widths 50 – 200 mm. Danger of death because the contact safety is endangered!
Pay attention to the cooling!

Length of cable
Twisted, shielded above 1 m cable length
max 5 m! (in conjunction with SIMODRIVE POSMO SI/CD/CA, the guidelines correspond to the User Manual SIMODRIVE POSMO SI/CD/CA)

Equipotential bonding cable is routed along the mounting panel close to the P600/M600 conductors.

1) The drive group has more than six drive axes. This is the reason that round drive bus cables are used in the complete group. Further, the shields of those round drive bus cables that are used to jumper/bridge “Gaps in the module group” must be clamped/connected to the associated module housing!

Fig. 9-7 Connection example, two-tier configuration

Data on the system design

1. The continuous equipment bus cable of a drive group at one input module or monitoring module may be a maximum of 2.1 m long (from the supply point). For a two-tier configuration, two equipment bus branches, each with max. 2.1 m length from the branching point (supply point) can be used at the infeed.

2. 1500 mm equipment bus extension for a two-tier configuration with a branch at the supply/infeed point (Order No.: 6SN1161–1AA00–0AA1).

3. The drive bus length may not exceed 11 m.
For more than six modules, control units, round cables must be used instead of ribbon cables.

Note
Connection details for the DC link adapter set, refer to the dimension drawing in Fig. 12–59.
9.2 High–voltage test in the system

It is permissible to perform a high–voltage test on SIMODRIVE 611 drive converters.

The components are designed/dimensioned in compliance with DIN EN 50178.

The following secondary conditions/limitations must be carefully observed when the system is subject to a high–voltage test:

1. Power–down the unit.
2. Withdraw the overvoltage module in order to prevent the voltage limiting responding.
3. Disconnect the line filter so that the test voltage does not dip.
4. Connect M600 to PE through resistor 100 kΩ (the grounding clip in the NE modules is open). In the factory, the units are subject to a high–voltage test at 2.25 kV\textsubscript{DC} phase–PE. The NE modules are shipped with the grounding clip open.
5. The maximum permissible voltage for a high–voltage system test is 1.8 kV\textsubscript{DC} phase–PE.

If these points are not carefully observed, then the modules can be damaged (preliminary damage).
9.3 Safety of machinery – safety–related parts of controls according to EN ISO 13849–1:2008

9.3.1 General information

With the introduction of EN 62061 and EN ISO 13849–1 as successor to the EN 945–1 standard, several things have changed regarding the assessment of suitable safety technology. Not only is the structure of a safety–related circuit taken into consideration, as was previously the case according to EN 954–1, but beyond this, the performance of the safety technology is also assessed along with the reliability; and if necessary, the software and many other related issues.

9.3.2 Safety–related stop functions of electric drive systems according to DIN EN 61800–5–2

Safety function STO – Safe Torque Off

Function

The Safe Torque Off (STO) function is a safety function to avoid unexpected starting. This function prevents the unexpected starting of a motor, connected to the drive control unit, from standstill. When the Safe Torque Off function is activated, the motor shaft cannot generate a torque.

Activation

This safety function should only be activated after the drive has come to a standstill, otherwise it loses its braking capability.

The standstill of the drive as well as the activation of the Safe Torque Off function must be realized and secured using an external machine control. If the drive is at a standstill and the Safe Torque Off function is active, additional brakes may be required for dangers due to the fact that the drive shaft is subject to an external torque.

For SIMODRIVE 611, the Safe Torque Off function is a “Device to shut down and avoid unexpected starting” according to EN 60204–1 Section 5.4. This behavior corresponds to stop Category 0, according to EN 60204–1:2006.

There is no electrical isolation from the line supply with the Safe Torque Off function. As a consequence, this function does not represent a protective device against electric shock.

Safety function SS1 – safe stop (time controlled)

Function

Initiates that the motor decelerates, and after an application–specific delay, initiates the STO function.

This behavior corresponds to stop Category 1, according to EN 60204–1:2006.
Implementation for the drive system SIMODRIVE 611
digital and universal

Closed-loop control
On the control modules, which are inserted into the power module, each control module is equipped with a safety relay to implement the STO function. For double-axis modules, the safety relay acts on both axes.

Line infeed
Everyline infeed includes an integrated main contactor, which can be used for the Safe Torque Off function (STO).

9.3.3 Control modules safety-related circuit

![Diagram of SIMODRIVE 611 internal block diagram of the STO function](image)

Fig. 9-9 SIMODRIVE 611 internal block diagram of the STO function
The power unit controls the power feed to the individual motor windings.

The gating logic on the control module clocks the 6 power transistors using a specific pattern to generate a rotating field. An optocoupler is connected between the gating logic and each control amplifier of a power transistor to provide electrical isolation. Power supply P5 of the optocoupler is fed via the NO contact of safety relay K1. When the Safe Torque Off function is activated, the NO contact of the safety relay is opened and the NC contact (= feedback contact) is closed. The NO and NC contacts in the safety relay are positively driven. The state of the safety relay (NO contact) must be evaluated via the feedback signal contact AS1/AS2.

Control

When the Safe Torque Off function is active (in the normal state without fault) the contacts of the NO contact –K1 are open and the power supply to the optocouplers is interrupted.

In order that the control module of the SIMODRIVE 611 identifies the state Safe Torque Off, and processes it in the sequence control, the logical signal level of terminal 663 is signaled to the control module via an optocoupler. If the Safe Torque Off function is active, this input immediately generates a pulse inhibit via the control logic.

The feedback signal contact of the safety relay must be evaluated in every case and must be used to directly control a second shut off signal path.

![Diagram of SIMODRIVE closed-loop control STO control block diagram](image)

Table 9-2 Value integrated safety relay

B100 value of the integrated safety relay: 20,000,000 operating cycles, service life: 20 years.
9.3.4 Safety–related circuit infeed modules

**Function**

Every line infeed has an integrated main contactor, which can be used for the Safe Torque Off function (STO).

![Diagram of line infeed control line contactor](image)

Fig. 9-11 Line infeed control line contactor, block diagram

The internal circuit of the line contactor via terminal 48 is shown symbolically. The control logic of the line and pre-charging contactors has a somewhat complex design, in order to guarantee a defined switch–on and switch–sequence.

Before interrupting the connection NS1–NS2, the line contactor must always be opened via terminal 48, or must be opened at the same time. The jumper between NS1 and NS2 when the unit is shipped must be removed.

B₁₀₀ value of the integrated line contactor: 1,333,333 operating cycles

Service life: 20 years
9.3.5 Safety functions

Description

With the SIMODRIVE 611 converter system, using the appropriate circuit, the following safety stop functions can be implemented:

<table>
<thead>
<tr>
<th>Function</th>
<th>Designation according to IEC 61800–5–2</th>
<th>Previous designation</th>
<th>Previous description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Safe standstill</td>
<td>Safe torque off</td>
<td>STO</td>
<td>SH</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Safe standstill</td>
</tr>
<tr>

</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Stop Category 1</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Fast stop</td>
</tr>
</tbody>
</table>

It should be noted that the safety functions only represent a very small part of the device functions.

A two-channel structure with suitable fault identification for the safety functions can be configured by using an appropriate circuit.

In order to implement the Safe Torque Off safety function in two channels, the line contactor integrated in the infeed modules as well as the safety relay integrated in the control modules should be used. The positively driven NC contacts of the line contactor and the safety relay should be evaluated as feedback signal.

The line fuses and feeder components should be selected and dimensioned according to the regulations as specified in Catalog NC60 as well as the Configuration Manual.

Main switch –Q0 is used as line disconnection device according to EN 60204–1:2006 and is not considered in the sense of functional safety.

There is no electrical isolation from the line supply with the Safe Torque Off function. As a consequence, this function does not represent a protective device against electric shock.

The safety functions integrated in the SINUMERIK 840D pl (SINUMERIK Safety Integrated) in conjunction with the SIMODRIVE 611D modules are not part of this documentation.

The CNC control modules SINUMERIK 840D have no influence on the evaluation of the safety functions.
9.3.6 Principle of STO in a safety function

A safety function essentially comprises two subsystems:

- SENSE
- EVALUATE
- RESPOND

Every safety function must be configured using suitable sensors, logic units and actuators.

The SENSE and EVALUATE subsystems are not considered in any more depth here. The selection and installation of the components must conform to the requirements of the safety function to be implemented.

The RESPOND subsystem in principle has a two channel structure. The first channel includes the safety relay –K1 of the drive. This operates according to the pulse shutdown principle with monitoring.

Line contactor –K2 forms the second channel, which is integrated in the line infeed. The line contactor is monitored using positively-driven NC contacts.

As an alternative to integrating the line contactor, it is also possible to use a motor contactor for each motor as the second safety-related channel. The calculation results of the following application examples can be analogously applied.
9.3.7  Principle of SS1 in a safety function

The SS1 safety function can also be achieved by using the STO safety function as basis and then adding a supplementary circuit. Also in this case, a basic two–channel architecture is configured.

**SENSE**

The SENSOR subsystem can have the same structure as described in Chapter 9.3.6.

Activating the safety function using the SENSE subsystem immediately initiates that the drive is stopped through a single channel. At the same time, a safe timer is started in EVALUATE.

The drives can be stopped, for example, by ramping–down the drives in a controlled fashion via the NC program, by inhibiting the drive enable terminal 64 or the axes–specific control enable, terminal 65.

The OFF delay of the timer should be set so that the drive has come to a standstill along the fast stopping ramp before this delay time has expired. After the timer has expired, the drive is safely switched into a no–torque condition according to Chapter 9.3.6.

**EVALUATE**

The EVALUATE subsystem must be expanded by a safety–related OFF–delay.
9.4 Application examples

General

For all SIMODRIVE devices the basic principle of the safety–related circuit is the same. However, the different devices can have different terminal designations. The following circuit examples can be used, in an adapted form, for all SIMODRIVE infeeds and drives. The specifications to prove the Performance Level can be kept.

For reasons of transparency, in the following examples, only the safety–related terminals are connected. To move the drives, all of the necessary enable terminals must be supplied.

In the following examples, power contactors with mirror contacts as well as contactor relays with positively–driven contacts are used. For reasons of simplicity, the mirror contacts of the power contactors are designated as standard as positively–driven contacts.

9.4.1  EMERGENCY STOP at a converter → SS1

**Requirement**

The supplementary safety function EMERGENCY STOP results in the drive being safely stopped in a controlled fashion. After the stopping time has expired, the drive is safely switched into a no-torque condition.

**Assumption**

The EMERGENCY STOP pushbutton is actuated 1x per month.

As a result of the risk assessment, the required Performance Level for the safety function is defined to be PLr = d.

---

Fig. 9-14  EMERGENCY STOP at a SIMODRIVE 611 converter → SS1 at the drive
Prerequisite

Is required to charge the DC link and move the drive:

- EMERGENCY STOP is released and the safety relay –A1 is reset via push-button –S1.
- Safety relay –K1 and line contactor –K2 are controlled by the contacts of safety relay –A1.

Actuating EMERGENCY STOP

- The instantaneous contacts of safety relay –A1 are opened. The axis-specific control enable RF (terminal 65) is switched to low. The drive is immediately braked to zero speed at the current limit.
- After the delay time of –A1 has expired, safety relay –K1 and line contactor –K2 are switched into a no-voltage state. The NO contacts open, and the motor is disconnected from the torque-generating power supply through two channels.
- This behavior corresponds to stop Category 1, according to EN 60204–1:2006.

Limitations

- If the pulses are canceled before the drive comes to a standstill, then it coasts down.
- Suspended/hanging axes must be secured using holding brakes or similar.

Block diagram

![Block diagram of the supplementary EMERGENCY STOP safety function](image-url)
SENSE subsystem

The safety functions are initiated by the EMERGENCY STOP pushbutton, which can be released by turning, and which is connected through two channels. This has positively opening contacts.

Fault exclusion is assumed for the positively opening contacts as well as for the mechanical system of the EMERGENCY STOP pushbutton. An accumulation of faults between two consecutive actuations of the EMERGENCY STOP pushbutton can result in the safety function being lost. This behavior corresponds to Category 3.

</tr>
</tbody>
</table>
RESPOND subsystem

The RESPOND subsystem has a two channel structure. The first channel is implemented using safety relay –K1. The line contactor in the line infeed forms the second channel. Both channels are simultaneously controlled from safety relay –A1. The positively opening NC contacts of the contactor and relay are tested as feedback signal contacts by –A1 at each start.

An accumulation of faults between two consecutive actuations of the EMERGENCY STOP pushbutton is not detected:

- Basic as well as well-proven safety principles – such as the requirements regarding Category B – are maintained. Protective circuits are provided.
- When a component fails, the safety function is always maintained. The failure is detected.

This structure corresponds to Category 3, according to EN 13849–1:2008.

As a consequence, the requirements regarding PLd with Category 3 for the supplementary EMERGENCY STOP safety function are fulfilled.

#### 9.4.2 EMERGENCY STOP and protective door monitoring at a converter → SS1

**Requirement**

a) Opening the protective door stops the drive in a controlled fashion. After the stopping time has expired, the drive is safely switched into a no–torque condition.

b) The supplementary safety function Emergency Stop results in the drive being safely stopped in a controlled fashion. After the stopping time has expired, the drive is safely switched into a no–torque condition

As a result of the risk assessment, the required Performance Level for both safety functions is defined to be PLr = d.

When the protective door is open, in normal operation, the DC link voltage should be kept.
Fig. 9-16  EMERGENCY STOP and protective door monitoring at a SIMODRIVE 611 universal converter – SS1 at the drive
Preconditions to operate/move the drive

- EMERGENCY STOP has been released and safety relay –A1 has been reset.
- Protective door is closed (position switch contacts –S4 and –S5 are closed).
- Safety relay –A2 is automatically started.
- Safety relay –K1 is controlled via the NO contact of –K6, from the instantaneous output (14) of safety relay –A3.
- Line contactor –K2 is controlled via the contacts of –K5 using contactor relay –K4, from the delayed output (28) of safety relay –A3. The drive DC link is charged.
- The control enable on the control module has a high signal from safety relay –A2.

The protective door is opened

- EMERGENCY STOP has been released and safety relay –A1 has been reset.
- The cascading input of –A2 has a high signal.
- When the protective door is opened, the position switch contacts –S4 and –S5 are opened.
- The instantaneous output (14) from –A2 supplies a low signal at the drive controller enable. → The motor is stopped at the current limit.
- After the selected time at –A2 has expired, the delayed output (28) switches the cascading input (1) from –A3 to a low signal level.
- The instantaneous output (14) of –A3 switches–out (de–energizes) safety relay –K1 via –K6. (the drive pulses are canceled and in turn the energy feed to the motor is interrupted).
- The NC contact of –K1 controls contactor relay –K3. The NO contact of –K3 in parallel with –K4 closes and keeps line contactor –K2 connected to the power supply via –K5.
- After the time selected in –A3 expires, the delayed output (28) switches–out (de–energizes) contactor relay –K4. Line contactor –K2 remains controlled (energized) from –K5 via –K3. The DC link remains charged via terminal 4.

Closing the protective door

- –K1 is automatically controlled (energized) from –K6 via –A3.
- –K2 is again controlled (energized) from –K5 using –K4 via –A3.
- High signal at the controller enable input of the drive. → motor can be operated again.
Actuating EMERGENCY STOP

- The instantaneous output (14) of safety relay –A1 is de-energized, and therefore the cascading input (1) of –A2 is deactivated. –A2 behaves just the same as when opening the protective door.

- After the selected time at –A2 has expired, the delayed output (28) switches the cascading input (1) from –A3 to a low signal level.

- The instantaneous output (14) of –A3 switches-out (de-energizes) safety relay –K1 via –K6. (the drive pulses are canceled and in turn the energy feed to the motor is interrupted).

- The delayed output (28) of –A1 switches-out (de-energizes) line contactor –K2 after the selected time.

This behavior corresponds to stop Category 1, according to EN 60204–1:2006.

Secondary conditions

- The drive must be stopped within the delay time set at –A2. If the pulses are canceled before the drive comes to a standstill, then the drive will coast down.

- The time at –A3 should be set as short as possible, however so that –K3 pulls in before –K4 drops out in order to avoid that line contactor –K2 drops out.

- The delay time at –A1 should be set the same as the time of –A2.
Safety function, protective door

If the protective door is opened, the drive should be safely stopped and after a safely monitored time, should be shut down.

Assumption

In two–shift operation, the protective door is opened every 10 min. The plant is operational from Monday to Friday. The number of actuations is as follows:

- 6 • 1/h • 16 h/d • 260d = 24960 per year.h.

![Block diagram of the safety function, protective door](image)

Safety relay –A1 is used for the diagnostics of –K2, –K3 and –K5. It is not included in the calculation for the protective door safety function.

SENSE subsystem

The protective door is monitored using two independent position switches –S4 and –S5. Both position switches have a positively opening contact.

RESPOND subsystem

The RESPOND subsystem has a two channel structure. The first channel comprises safety relay –K1 and contactor relay –K6. Line contactor –K2 and contactor relays –K3, –K4 and –K5 form the second channel.

In this example, the RESPOND subsystem has a two channel structure with different demand rates per channel. A dangerous fault in channel 1 means that channel 2 is immediately called with its monitoring options.

Components –K1, –K3, –K4 and –K6 are tested by –A2 or –A3 at each start. Contactor –K2 and contactor relay –K5 are tested by –A1 at each start.

An accumulation of faults in channel 2 between two consecutive actuations of the EMERGENCY STOP pushbutton is not detected.

- Basic as well as well–proven safety principles – such as the requirements regarding Category B – are maintained. Protective circuits are provided.
- Protective circuits are provided.
- When a component fails, the safety function is always maintained.
- The failure is detected.

This structure corresponds to Category 3, according to EN ISO 13849–1:2008.

\]

Determining the Performance Level

- Structure of the SRP/CS corresponding to Category 3
- MTTF_d is high
- DCavg is average
- sufficient measures against common cause failures

Acc. to EN ISO 13849–1:2008 Annex K \( PLe \) mit \( PFH_d = 4.29 \times 10^{-8} / h \) is attained.

Measures against common cause failures CCF of the safety function

According to EN ISO 13849–1 Annex F, for SRP/CS from Category 2, a minimum of 65 points is required.

The considerations according to Chapter 9.4.1 Table 9-9.

This means that in total, the adequate number of 65 points is reached.

As a consequence, the requirements regarding PLd with Category 3 for the protective door safety function are fulfilled.
Supplementary safety function, EMERGENCY STOP

If EMERGENCY STOP is actuated, then the drive should be safely stopped and shut down.

Assumption

The EMERGENCY STOP pushbutton is actuated 1x per month.

The consideration for this safety function can be basically realized corresponding to the description in Chapter 9.4.2 “Protective door safety function”. However, the EMERGENCY STOP pushbutton as well as safety relay –A1 must also be taken into account for this safety function.

The position switches to monitor the protective door do not play a role when considering/analyzing EMERGENCY STOP.

Fig. 9-18   Block diagram of the supplementary EMERGENCY STOP safety function

SENSE subsystem

The safety functions are initiated by the EMERGENCY STOP pushbutton, which can be released by turning, and which is connected through two channels. This has positively opening contacts.

Fault exclusion is assumed for the positively opening contacts as well as for the mechanical system of the EMERGENCY STOP pushbutton. An accumulation of faults between two consecutive actuations of the EMERGENCY STOP pushbutton can result in the safety function being lost. This behavior corresponds to Category 3.

EVALUATE subsystem

The EVALUATE subsystem of the supplementary EMERGENCY STOP safety function is in this case realized using three SIRIUS 3TK3842 safety relays. The safety relays have instantaneous and delayed enable circuits.

Safety relay –A1 is used to evaluate the EMERGENCY STOP pushbutton. Devices –A2 and –A3 are used to provide a safety–related time delay when switching off and are controlled from –A1 via the cascading input, terminal 1.

</tr>
</tbody>
</table>

RESPOND subsystem

When actuating EMERGENCY STOP, the power supply of line contactor –K2 as well as contactor relay –K1 are shutdown (de–energized) via the delayed output (28) from –A1. When requesting EMERGENCY STOP, contactor relays –K3 and –K4 therefore have no influence on the correct function of –K1 and –K2.

Component –K1 is tested by –A2 via –K3 at each start. Contactor –K2 is tested by –A1 at each start.

An accumulation of faults in channel 2 between two consecutive actuations of the EMERGENCY STOP pushbutton is not detected.

- Basic as well as well–proven safety principles – such as the requirements regarding Category B – are maintained. Protective circuits are provided.
- When a component fails, the safety function is always maintained. The failure is detected.

This structure corresponds to Category 3, according to EN ISO 13849–1:2008.

As a consequence, the requirements regarding PL_d with Category 3 for the protective door safety function are fulfilled.
9.4.3 EMERGENCY STOP and protective door at several converters → SS1

Requirement

a) Opening the protective door stops quickly stops the drives. After the stopping time has expired, the drives are safely switched into a no–torque condition.

b) The supplementary safety function EMERGENCY STOP results in the drives being quickly stopped. After the stopping time has expired, the drives are safely switched into a no–torque condition.

As a result of the risk assessment, the required Performance Level for both safety functions is defined to be PLr = d.

When the protective door is open, in normal operation, the DC link should be kept.
Fig. 9-19  EMERGENCY STOP and protective door monitoring at several SIMODRIVE 611 universal converters – SS1 at the drives
Safety function, protective door

If the protective door is opened, the drive should be safely stopped and after a safely monitored time, should be shut down.

Assumption

In three-shift operation, the protective door is opened every minute. The plant is operational from Monday to Sunday. The number of actuations is as follows:

60 • 1/h • 24 h/d • 365d = 525600 per year.

Fig. 9-20 Block diagram of the safety function, protective door for six axes

Safety relay –A1 is used for the diagnostics of –K2, –K3 and –K5. It is not included in the calculation for the protective door safety function.

SENSE subsystem

The evaluation of the SENSOR subsystem is explained in Chapter 9.4.2 “EMERGENCY STOP and protective door monitoring at a converter → SS1”

The higher number of switching cycles has no influence on the evaluation of this subsystem.

The results are taken over and used.

EVALUATE subsystem

The evaluation of the EVALUATE subsystem is explained in Chapter 9.4.2 “EMERGENCY STOP and protective door monitoring at a converter → SS1”.

The results are taken over and used.

RESPOND subsystem

The RESPONSE subsystem is essentially structured as described in Chapter 9.4.2 “EMERGENCY STOP and protective door monitoring at a converter → SS1”. Only the additional safety relays in channel 1 must still be taken into consideration.

<td>$&lt;1 \times 10^{-6}$ / h</td>
</tr>
</tbody>
</table>

As a consequence, the requirements regarding PLd with Category 3 for the protective door safety function are fulfilled.

**EMERGENCY STOP safety function**

This safety function corresponds, regarding its implementation, the explanation and information given in Chapter 9.4.2 "Supplementary safety function EMERGENCY STOP for an axis". Only in the RESPOND area, in channel 1, the additional safety relay –K1 has been added. This must also be taken into account when calculating the RESPOND subsystem.

The SENSE and EVALUATE subsystems are not affected by this.

The logic component of the described safety functions can be implemented using programmable safety components, such as a fail–safe PLC systems, or the modular MSS safety system.

The safety relays can be monitored using software in the logic section. This means that the contactor relays can be eliminated.
9.5 Using programmable safety components

The safety functions are calculated analogously to the previous examples using discrete safety relays.

Fig. 9-22  Design with the safe programmable logic
Connection Diagrams

Note
The following connection diagrams only show the terminal connections. Further, external components are not completely shown. Refer to Chapter 8.

The following comments should be observed in the connection diagrams:
1. The jumper may only be removed in conjunction with the start inhibit.
2. Not available for unregulated infeed.
3. Connect with terminal 19 of the NE module.
4. Drive bus – round cable
5. Drive bus – ribbon cable
6. Drive bus – terminating connector
7. For an external pulsed resistor, remove jumper 1R/2R.

1) Fan replacement possible from MLFBs with final number 2 and higher. MLFB final number < 2 means that the fan must be replaced by Siemens service!

2) Fan cannot be replaced

3) MLFB for standard mounting fans. Order designation for replacement fans, pipe cooling: GWE–000000587915. For additional spare/replacement parts of the pipe cooling, refer to the dimension drawings.

4) 2x are required
Removing the fan

1. Switch off the line current supplies (I/R module) or DC link voltage (PM module). **Wait at least 30 minutes for the DC link energy to discharge!**
2. Verify that the fan is isolated from the supply (line supply input and DC link)
3. Remove the components from the drive group.
4. Open the fan cover

<table>

</thead>
</table>

5. Taking out the fan
6. Loosen the cable connector

Installing the fan

1. Before installing the fan, check the air flow direction (the arrow on the fan must point towards the cooling ribs).
2. Insert the cable connector until it fully engages.
3. Introduce the fan until it fully engages.
   **The connecting cables must not be interchanged!**
4. Close the fan cover.

11.4 Inspection of the DC link capacitors of the PM modules

**Caution**

After the devices have been non-operational in a no-voltage condition for more than two years, the DC link capacitors must be reformed. If this is not done, when the devices are switched on they can be damaged.

**Date of manufacture**

The production date can be derived from the following assignment to the serial number (e.g. S T-S9 für 2004, September):

<table>
<thead>
<tr>
<th>Key</th>

</tbody>
</table>

The serial number is stamped on the type plate.

When forming, the DC link capacitors are subject to a defined voltage and a limited current. This means that the internal relationships required for the DC link capacitors to function are restored.

**Note**

It is important that the storage period is calculated from the date of manufacture and not from the date that the equipment was shipped.
11.4 Inspection of the DC link capacitors of the PM modules

**Forming circuit**

The forming circuit is configured using incandescent lamps, or alternatively using PTC resistors.

Components required (recommendation):

- 1 fuse switch 3x 400 V / 10 A
- Cable, 1,5 mm²
- 3 PTC resistors 350 R / 35 W (Recommended: PTC–35W PTC800620–350 Ohm, company, Michael Koch GmbH; [www.koch–mk.de](http://www.koch–mk.de))
- 3 incandescent lamps 230 V / 100 W
- Various small parts, such as lamp sockets, etc.

**Danger**

As a result of the DC link capacitors, after the device has been disconnected from the supply, voltages are present in the device for up to 5 min. It is only permissible to work on the device or the DC link terminals at the earliest after this wait time has expired!

![Forming circuit comprising power modules with incandescent lamps](image-url)
Before forming the DC link capacitors, it is imperative that the DC link bridge is removed.

Ensure that the power module does not receive a switch–on command.

Connect the forming circuit.

Over the course of the forming time, the incandescent lamps must become darker/go out completely. If the incandescent lamps are continually lit, then there is a fault in the power module the wiring.

When forming using PTC resistors, the modules must remain in the circuit for approximately 1 hour. If there is a fault in the power module, then the resistors will become very hot (surface temperature > 80 °C).

- **Volume Flow**:
  - At 480 V/60 Hz/330 Pa: 455 m³/h
  - At 400 V/50 Hz/250 Pa: 400 m³/h
- **Rated Speed**:
  - At 480 V/60 Hz: 2850 min⁻¹
  - At 400 V/50 Hz: 2500 min⁻¹
- **Lubrication System**: Ball Bearing
- **Permissible Ambient Temperature**:
  - At 50 Hz: ±100 °C
  - At 60 Hz: ±80 °C
- **Service Life**: Approximately 40,000 hours
- **Weight**: 4.5 kg

**Delivery Condition**

- Fan ready for delivery, individually packed in a carton. 
- Adhesive labels: GWE-Snr. 462008.0128.50 on fan and GWE-Snr. 462008.0231.00 on packaging (free of charge)
- Labeling with: SIMODRIVER radial fan A5E001073366

**Etiketten-Anschlussplan**

1. Positions 2, 3, 6, 7 and 10 are included in the package and attached to the fan with adhesive tape.
2. Adhesive label GWE-Snr. 462008.0231.00 on packaging
3. Adhesive label GWE-Snr. 462008.0128.50 on fan

Example of shield connection plate mounting and connection of cable screen for a 150 mm module.

**Montage:**
- The shield connection plate is hung in the module grille and secured with module attachment screws.
- The details are given in the table below.

**Shield connection plate mounting:**
- The shield-connection plate is hung in the module grille and secured with module attachment screws.
- The connection is no strain relief.
- The hose-clamps match the outside diameter of the cable screen.
- The hose-clamps are included with Siemens preassembled motor cables.

Fig. 12-62  Shield connection 6SN1162–0FA00–0AA2 (dimension drawing)
Mounting instructions

The thermally conductive plate can be mounted at any position on the device group. Ensure that the plate is approx. 100 mm wide and so extends over a neighboring device. It does not matter whether the plate extends to the right or the left. The division of the rear-side breakouts to fasten the thermally conductive plate takes account of this. The thermally conductive plate together with the device fastening is screwed to the rear wall. This does not impair the bus lines and DC link connections.

Fig. 12-63 Thermally conductive plate 6SN1162–0BA01–0AAx (dimension drawing)

Certificates

You can find the EC declaration of conformance for the machinery directive, the EMC directive and the Low-Voltage-Directive in the Internet at:

http://support.automation.siemens.com/WW/view/de/32151216
Certification Number: 664.EMNI1113.02.001
Entry ID: 25447747

There, as search term, enter the number 25447747 or contact the local Siemens office in your region.

---

Note

Listing and file names regarding UL/CSA/FM certification of SIEMENS SIMODRIVE products can be found under:

http://support.automation.siemens.com

There, as search term enter "SIMODRIVE certificates".

---

Note

Certificates, Declarations of Conformity, test certificates, such as CE, UL, Safety Integrated, etc., are valid only when the components described in the associated catalogs and this configuration guide are used, and installed in accordance with the configuring guidelines and used properly!

In other cases, such documents must be prepared again by the vendor of these products!

Product description: SIMODRIVE 611
(for included hardware and software releases see annex)

The above mentioned product may be used in systems in order to implement the
functional safety functions "Safe Stop" (STO) and "Safe Stop 1" (SS1) that fulfill the
requirements of PLe and category 3 according to [1]. The function STO and SS1
correspond to stop category 0 and stop category 1 according to [2], respectively.

</table>
2 Restrictions

The “Safe Stop” (STO) function prevents unexpected starting of a connected motor from standstill. The “Safe Stop” (STO) shall be activated only when the drive is at standstill, otherwise, it loses its ability to brake the motor.
3 Boundary Conditions
In order to achieve PLe and category 3 for the safety functions STO and SS1 in systems including the described SIMODRIVE 611 modules a dual channel architecture must be implemented by using the listed infeed modules as described in the related application examples.

C-485
EMC limit values in South Korea

The EMC limit values to be complied with for South Korea correspond to the limit values of the EMC product standard for variable-speed electric drives EN 61800–3, Category C2 or limit value class A, Group 1 according to EN55011.

By applying suitable supplementary measures, the limit values according to Category C2 or according to limit value class A, Group 1 are maintained. Further, additional measures may be required, for instance, using an additional radio interference suppression filter (EMC filter).

The measures for EMC-compliant design of the system are described in detail in this manual respectively in the Installation Guideline EMC.

Please note that the final statement on compliance with the standard is given by the respective label attached to the individual unit.

SIMODRIVE 611 digital, 10-390
SIMODRIVE 611 universal HRS, 10-391
SIMODRIVE 611 universal HRS2, 10-391
Tightening torque for screws retaining electrical connections, 2-41
Toolbox, 4-93
Toothed-wheel encoder, Ordering notes, 3-81
Transformers, 7-216
Typical circuit diagram
with SIMODRIVE 611 digital, 8-304
with SIMODRIVE 611 universal HRS, 8-305
with SIMODRIVE 611 universal HRS2, 8-305

U
UI module, 6-145
5 kW, 6-154
Commutating reactor(s), 6-180
Line choke, 6-180
Technical specifications, 6-173
Using the manual, viii

V
Variants
of the control board, 4-93
of the option modules, 4-93
Voltage limiting module, 8-331
VP module, 2-48
VPM, 2-48
VPM 120, 8-331
VPM 200, 8-331

W
Warnings, viii
Warranty, 1-28
